From the study of the morphologic and cultural char- coccus, from other simulating or closely related organ- and absorption experiments the principal organisms encountered are divided into typical pneumococci on the one hand and typical streptococci on the other. In addition there were isolated a large number of related organisms which will require further study before they can be classified satisfactorily.

While the work of various foreign and domestic investigators left little doubt that a certain percentage of normal individuals harbor pneumococci in their mouths, it seemed desirable to repeat these observations in the light of recent developments in our knowledge of the biology of pneumococci and streptococci. The work of the commission leaves no doubt that about 50 per cent. of healthy persons harbor typical pneumococci in their mouths. Thus in one series of 78 "normal" cases the pneumococcus was found in 50 per cent.

In the majority of cases when pneumococci were not found streptococci were isolated. These, together with influenza-like organisms, were sometimes associated with the pneumococcus.

If positive conclusions can be drawn from a comparatively small series of cases we may infer that a greater percentage of individuals in crowded centers harbor the pneumococcus than in country districts; and that though some may always harbor virulent pneumococci, others, as a general rule, are more apt to do so in the winter months than in the fall or spring. And this seems in accord with what is known concerning the transmission and viability of the pneumococcus. It would seem necessary to continue these studies with special reference to the occurrence of pneumococci in the throats, as well as in the mouths of human beings.

In testing the virulence of the strains isolated from various sources, the technic of one investigator varies so much from that of another that it is impossible to correlate statistics on this point. In one series, in which a uniform procedure was carried out by the subcutaneous inoculation of rabbits (chiefly) with "mass cultures," the following percentage of virulent strains was found:

Amount Inoculated.	Pneumonia Cases.	Healthy Individuals.
4.0c.c.	87 per cent.	69 per cent.
0.1c.c.	51 per cent.	31 per cent.

In another series, in which 51 cultures of mouth pneumococci were tested by injecting white mice subcutaneously with the second "generation" grown for 24 hours on serum agar slants, 78.5 per cent. were virulent and 21.5 per cent. avirulent. About the same proportion of avirulent pneumococci were found in the mouths of pneumonia patients (77 per cent.) as in the mouths of normal individuals (79 per cent.). Reasoning from analogy, pneumococci from cases of pneumonia are probably of increased virulence for human beings and, since the virulence (*for experimental animals*) of pneumococci from normal cases can be rapidly increased, it becomes clear that all possible measures should be taken to restrict the dissemination of pneumococci by prohibiting public expectoration. In connection with this, the suggestion is made that the value of various lotions in ridding the mouth and throat of pneumococci and other pathogenic bacteria merits careful investigation.

There seems to be some evidence opposing the belief that pneumococci are permanent inhabitants of the human mouth, except possibly in the case of certain individuals. It was found that they may persist for days or weeks in the mouths of patients who have recovered from pneumonia, and individuals who have been repeatedly found "negative" may acquire the pneumococcus by association with pneumonia or with "positive normal" cases.

---

[1] Jour. of Exp. Med., 1905, vol. vii, No. 5, pp. 401-632.

The very complete study of the important question of the viability of the pneumococcus shows that its life duration in moist sputum, in the dark at room temperature, averages less than two weeks (11 days); and in strong light less than 5 days. In dried sputum in the dark it lives for an average of 35 days; in diffuse light, 30 days; in sunlight, less than 4 hours. In powdered sputum, even when kept in the dark, the death of the pneumococcus takes place in from 1 to 4 hours, and if exposed to sunlight death ocurs within an hour. When dried on cloth it lived slightly longer than on non-absorbing surfaces, such as glass, tin or wood. Moist sputum *en masse* may be considered innocuous except to persons handling recently contaminated clothing, bedding, etc. When such masses are dried and then powdered by sweeping, dusting, etc., the organisms do not remain long in suspension and die off within an hour in sunlight or diffuse daylight, or in about four hours in the dark. Danger of infection from powdered sputum may be avoided by free illumination and ventilation of the sick room and by the substitution of moist antiseptic cleansing for dry sweeping or dusting. Further, the experiments, as applied to the pneumococcus, support the theory largely advanced by Flügge and his coworkers—that the transfer of pathogenic bacteria from one person to another is possible by the aerial transmission of fine spray particles (Flügge's drop infection). In the act of coughing, sneezing, expectorating or talking, a pneumococcus host expels particles of sputum or saliva containing virulent pneumococci, which may remain suspended in the air for a number of hours if the ventilation of the room is good. Whether suspended or dried on surrounding objects, however, the pneumococci become harmless in about an hour and a half, while many in the spray succumb to strong light in a few minutes. This is time enough for pneumococci so expelled to become lodged in the mouth and throat of exposed persons. In the light of these experiments, it will be seen that the risk of infection is chiefly borne by those in direct contact with one harboring the pneumococcus. From the point of view of prevention, the great question seems to be how to get rid of pneumococci in the mouths and throats of persons convalescent from pneumonia.

We see that these studies concern especially the pneumococcus; they deal with one phase only of pneumococcus infection; the other side of the pneumonia question, the side presented by the patient, has not been considered.

CONTRIBUTIONS OF PHARMACOLOGY TO PHYSIOLOGY.

In his first Herter lecture[1] at the Johns Hopkins Medical School, Professor Hans Meyer of the University of Vienna calls attention to the biologic results that we owe to pharmacologic methods of investigation. He points out that drugs, i. e., chemical substances, penetrate into the interior of the body and reach parts inaccessible to scalpel and electric current, formerly the essential weapons of the experimental physiologist effecting there disturbances of function which, when correctly interpreted, throw desired light on difficult physiologic problems.

The first examples cited are the physiologic discoveries that have been made from the pharmacologic study of curara poison. Further, because it has been shown that centrifugal and centripetal nerve tracts react differently to poisons, it may be concluded that they are chemically different, although morphologically alike. Langley found that nicotin paralyzes the sympathetic ganglia and through them the preganglionic nerves, while the postganglionic escape; by this method it may be decided whether a nerve ends in a ganglion or passes through it.

From the fact that tetanus toxin, when injected into the extremity of an animal, is absorbed by the motor nerve endings and carried upward in axis cylinders into the spinal cord, we learn the hitherto unknown fact that there is constantly flowing through the axis cylinders of motor nerves a protoplasmic stream that reaches the neurocytes themselves, a fact of significance for nerve nutrition and the disturbances in central ganglia following nerve section. Meyer has found that there occurs a similar flow of diphtheria toxin in the nerves and the same thing may be true also of certain metals like lead. In case a centripetal stream like this passes along peripheral sensory nerves, its course is arrested by the spinal ganglia. If the posterior nerve roots between the ganglia and the cord are injected, however, there arises the so-called tetanus dolorosus, characterized by periodical, extremely painful seizures, thus showing the existence of special, central pain-subserving structures in the spinal cord.

As an example of the advance in knowledge of the physiology of glands made through the use of pharmacologic agents, Meyer, among other results, mentions the fact that recently Wertheimer and Lepage have shown that the pancreas possesses at least two distinct secretory mechanisms, namely, one which is excited by pilocarpin, physostigmin, or muscarin, and in this case the secretion does not contain enterokinase, and one which is stimulated by secretin and other substances, but in this case the secretion does contain enterokinase.

It has been found, further, that experiments with pilocarpin point to the secretion in the swimming bladder of fishes, of oxygen by the epithelial membrane, which differs from ordinary diffusing membranes in that it is not penetrable in either direction. Other experiments indicate that the alveolar epithelium of the lungs permits ammonia gas to pass into the blood but not outward from the blood.

The study of cardiac poisons has contributed much to our knowledge of the physiology of the heart, but details are not considered in this lecture.

---

[1] Science, Oct. 6, 1905.

Phloridzin diabetes and adrenalin glycosuria, the discovery of glycuronic acid in poisoning by camphor and of the relations of lactic and amido-acids to intermediary metabolism in phosphorus and arsenical poisoning are cited as illustrations of the influence of pharmacology on the study of metabolism. Indeed, numerous chemical processes of reduction and oxidation were first discovered through studies with chemical or pharmacologic agents. Herter's infusions of methylene blue have revealed with especial clearness the oxygen requirements of muscles and the avidity with which muscles appropriate oxygen from oxyhemoglobin and other reducible substances.

The degree of narcotic activity of alcohol, ether chloroform, etc., compares very closely to the solution—tension or affinity—of these substances for lipoid substances like lecithin, and it has been concluded from this that in the union of the lipoid substance with the narcotic lies the origin of narcosis and that the lipoid constitutes an integral part of the "life-center" of the cells.

Finally, Meyer dwells on the value of the pharmacologic method of study of fundamental cellular and biologic phenomena, and mentions the important results obtained by Loeb from the study of the effects of metallic ions on general life processes, particularly the production of heliotrophisms and of parthenogenesis by definite chemical agents and procedures.

From this abstract of Professor Meyer's lecture we see that pharmacology, in addition to its direct practical importance, has been the means of furthering our knowledge of various biologic processes and that by the pharmacologic method of study it seems possible slowly to reach a better insight into the chemical constitution of protoplasm and the chemical interpretation of its functions. Great interest has been taken in experimental pharmacology in this country and some of our first universities have full professorial chairs of pharmacology. On account of the general and medical importance of this branch of biology it is hoped that before long pharmacologic investigation may receive increased encouragement from the establishment of full professorships in those of our real universities in which pharmacology as yet is inadequately represented.

FAMILY TREMOR.

The occurrence of minor ailments of a hereditary character or with family grouping is of interest in connection with major diseases of a like familial distribution with which the minor ailments may possibly be interchangeable or represented in an abortive form. There are those who believe that the comparatively harmless migraine may thus be correlated with epilepsy, that periodic attacks of mental depression in healthy individuals correspond, in a sense, to the more severe periodic insanities, and that the rather rare hereditary or familial tremor may represent, *in petto,* as it were, Huntington's chorea.

Family tremor is perhaps less well known than many other family diseases, though Dana in this country was one of the first to describe it carefully. Occasional reference to the condition is found in the literature as early as the end of the eighteenth century, though the symptom-complex has been carefuly studied only in the last twenty years. Schmaltz[1] has recently called attention to the condition once more, and has reported one family in which thirteen tremblers occurred in four generations. Aside from the hereditary or familial element, the etiology of this form of tremor is obscure, though there is some evidence that the excessive use of stimulants by the ancestors of those affected may play at least a subsidiary part. A history of the immoderate use of coffee, alcohol, or tobacco in the ancestors is sometimes found, but these factors are so common and the disease so rare that some other condition must also be present. Some observers, and especially those of the French school, regard the tremor as merely one of the signs of a widespread nervous degeneration, and point out that evidence of this is usually present, though not always marked. Still, some families with the tremor may have relatives who are epileptics, or belong to that class of borderland individuals who are described as "peculiar." Sometimes the tremblers themselves exhibit signs of nervous instability, are subject to emotional crises, are intolerant of alcohol or tobacco, or are frankly neurasthenic. The disease is not transmitted, like hemophilia, from the female to the male line, but may come from either side of the house; indeed, it may appear as a family disease without transmission from the forbears, or, in rare instances, it may skip a whole generation to reappear in the descendants.

The tremor generally takes the form of a rhythmical vibration with slight excursions and a slow tempo of from three to nine movements a second. Occasionally choreiform movements may occur. The control over the tremor varies in different individuals, though in many instances it appears as an intentional tremor and may lead to the diagnosis of multiple sclerosis. Some of the patients, however, have been able to carry on occupations requiring great delicacy of touch, such as watchmaking. Häbler had a patient who was unable to raise a glass to his lips without spilling the contents, but was an excellent marksman. Psychic influences usually seem to increase the tremor. The hands are the parts mostly affected, the legs next, and lastly the face.

The condition is doubtless confused at times with the tremor of old age, or, if the tremor is of the intentional variety, with that of multiple sclerosis. Such confusion should not occur if the exquisite familial character of the affection is considered, and if the absence of disturbances of the special senses, apoplectiform seizures, and paresis is noted. The condition, though apparently rare, is probably not infrequently overlooked, for the disease in itself may cause but little inconvenience, especially in its milder form, and the tremor in such cases may be taken for that of alcohol or neurasthenia. Like many previously rare diseases, it will probably become more common after the attention of the profession at large has once been called to it.

CARCINOMATOUS OSTEOMALACIA.

According to Woodyatt, who describes a remarkable case of diffuse carcinomatous infiltration of the bones, with softening, in a woman of 40, the primary tumor being situated in the breast, carcinomatous bone metastases, which are of rather frequent occurrence, may develop as multiple, circumscribed nodules, in which osteoplastic processes have the upper hand, and more rarely as diffuse, soft infiltrations in which bone resorption occurs.[1] When fairly widespread, this latter form has been called carcinomatous osteomalacia (first described by Hawkins in 1841). Because carcinomatous osteomalacia, though a very rare condition, may be confounded with true osteomalacia and with ostitis deformans, it merits special notice. In six of the seven generalized cases unearthed by Woodyatt, the primary carcinoma was situated in the breast; in the seventh its seat appears to have been unknown. Whether the malacic changes in the bones in any way are due to substances elaborated by the mammary gland can not be said.

Further observations are necessary in order to determine whether carcinomatous osteomalacia is connected exclusively with carcinoma of the breast. Among the special symptoms of this form of osseous disease are rheumatic pains in the regions involved; the pains are commonly described as deep-seated and gnawing or burning in character. Sometimes there is tenderness on pressure. Eventually the bones may become pliable and great deformity ensue. Cachexia and secondary anemia develop as the result, in part at least, of carcinomatous invasion of the marrow. Numerous nucleated red corpuscles and myelocytes (6 per cent. in the cases reported by Woodyatt) may appear in the peripheral blood. Microscopically, the stroma of the osseous metastases is like that of carcinoma elsewhere. The stroma is in very clear relation to disappearing bone surfaces and fragments, but whether the bone is first softened by some chemical process and then replaced by stroma or the stroma cells attack healthy bone substance can not be definitely stated, according to Woodyatt. The rôle played by the carcinomatous cells themselves in the bone resorption is also, as yet, largely a matter of speculation. Generally there is a layer of stroma between the epithelium and the bone, so that the epithelial cells probably do not directly absorb bone.

There is no ground for the view expressed by von Recklinghausen that these cases in reality are cases of secondary bone carcinoma implanted on existing malacia. Probably there is first decalcification and softening of bone (halisteresis), the exact factors in which we do not understand, possibly it may be due to substances produced by the cancer cells, and this is then followed by removal of the changed bone by the stroma. Naturally, the exact chemical processes concerned in these complex changes as yet can not be determined.

THE GREAT AMERICAN FRAUD.

Elsewhere in this issue will be found extracts from the first paper on "patent medicines" which appears in *Collier's Weekly* October 7. We have only space for a part of the article, neither can we reproduce the illustrations, which are most telling. Physicians should read these articles and should do all they can to disseminate the contained information, especially for the reason that the public press, in the main, can be depended on to preserve a notable silence regarding the disclosures. Some points made by Mr. Adams deserve emphasis. First is the showing that fraud, well advertised, is the basis of the nostrum trade. Then, sundry folks will feel uncomfortable when they read his conclusion that testimonials are "the expression of a low order of intelligence." The most important of his disclosures is photographic evidence of the blackmailing method of suborning the public press, through the notorious "red clause" of the advertising contract, by which every country newspaper is compelled to fight against anti-nostrum legislation or at once to lose all its nostrum ads. Mr. Adams also shows how one of the best-known Chicago newspapers, in order to obtain a profitable nostrum advertisement, sent its reporters to secure "testimonials." Thus, for a little money, a daily paper of professed high ideals, active in reforming everybody else, entered into a conspiracy to swindle its readers. One of the investigator's telling points is in his inability to see any real difference between "patent medicines" and "proprietaries," and as a corollary he shows too truly that the medical press, as a whole, is as much under secret medicine control as is the daily and weekly newspaper. This layman's scorn for our subsidized medical press should stimulate us to work for a better condition of affairs.

THE PROPORTION OF NIGHT LABORS.

It is a common idea that the great proportion of labor cases terminate at night, especially after midnight. White,[1] after analyzing 1,500 cases, points out that the popular idea is probably erroneous. In his series of cases a very slight fraction over one-half terminated during the night. The difference was too slight to have any weight. As an explanation for the fallacy, he suggests that night cases, because they disturb sleep, attract more attention and make more impression than cases in the day time. He suggests the consideration of further statistics so that the truth or falsity of this popular idea may be definitely decided.

[1] American Journal of Obstetrics, October, 1905, p. 527.

BEHRING'S ALLEGED CURE FOR TUBERCULOSIS.

The newspaper reports concerning Professor Behring's alleged cure for tuberculosis do not contain anything that one is justified in regarding as definite or reliable. There is no basis of facts in the reports on which to build any idea as to the real nature of the curative substance. Indeed, there is no reason to believe that Professor Behring ever announced, in the manner reported, the possession of a sure cure of tuberculosis in man, the efficacy of which has been established. It is more likely that Professor Behring reported to the tuberculosis congress the results of investigations in the immunization of cattle against bovine tuberculosis with reference, perhaps, to the possible application of the same methods to human tuberculosis. Under these circumstances, we must await further developments with patience. The newspapers, naturally, have made of this all they possibly could, and we must read what is published in them with considerable allowance. The hint that Professor Behring is holding back information for commercial purposes it is hoped is not true, although the scandal connected with his name and the manufacture of Behring's antitoxin for diphtheria will be revived in the minds of many physicians.

TREES AND MALARIA.

Old notions die hard. In spite of the scientific proof of the origins of yellow fever and malaria, there are physicians in districts where these diseases abound that reject the mosquito theory and still believe in the old miasmic emanation ideas of malaria and the transmission of yellow fever through infected clothing and other articles. As for the laity, we can hardly expect them to be in advance of even the laggards of the medical profession, and in evidence of this we have the shotgun quarantine of the south and the spectacle of the governor of a state practically forcing the resignation of self-respecting health officers because they could not honorably carry out his panic-dictated directions. As regards malaria, the old notion that it is a swamp emanation still holds sway in certain quarters, as witness the following quotation from a lay journal relative to the planting of the sweet gum tree in public streets and parks. "These trees exhale a balsamic odor that is healthful and they are said to absorb malaria from the soil and convert it into healthy gases by the action of the balsam of the tree." How far the balsamic odors of these or any other trees will aid in the prevention of a mosquito pest may be a question, but there is undoubtedly a connection between tree growth and the absence of malaria in some regions, and therefore the above expressed idea, absurd as it is in a scientific point of view, has perhaps a remote sort of justification. Certain trees, like the eucalyptus, are said to act as drains to the soil and to have abolished malaria in certain regions in this way. Owing to the arrangement of their foliage, they are said to give less shade than other trees and therefore do not diminish the natural evaporation to so great an extent, but, though their special odors are, in a concentrated form, inimical to mosquitoes, their action in this particular way for reducing malaria can not, with our present knowledge, be very well estimated. The effects are perhaps sufficiently accounted for by the drying up of surface pools, etc., which accompanies their growth in large numbers. It has been proposed, indeed, to utilize the eucalyptus for this purpose along the route of the Panama canal. There is no sufficient warrant, however, for the expectation expressed by some that eucalyptus planting will eradicate malaria and control tropical floods in that region. There is need, however, of every possible aid in the combat with disease on the isthmus, and every little helps. There is no doubt that a eucalyptus forest would be far more sanitary than the natural dense tropical vegetation, especially in the conditions which follow the carrying out of such undertakings as the digging of an interoceanic canal.

LAY "MEDICAL SCIENCE AT FAULT."

One Richard Weightman, posing as a Washington correspondent of the Chicago *Tribune*, and probably of other newspapers, in times past and present has afforded much joy to medical readers of that paper by certain ponderous deliverances on things medical. Mr. Weightman is intensely antimedical, but he has no idea how funny he is at times. In the *Tribune* of October 4 he says: "The case of Captain . . . is a curious illustration of the rudeness with which destiny too often treats the best-laid horoscopes of medical science." He then relates that a naval medical board told "the captain" that he had Bright's disease, and how, after treatment and the lapse of four years, he finally passed the physical examination. "Now he 'ups and dies' of apoplexy without a word of warning from the oracles of science. Amazing are the manifestations of sapience in the various learned professions." What odd pranks does ignorance play with a man's discretion! The poor newspaper simpleton, totally ignorant of the meaning of the terms "Bright's disease" and "apoplexy," which he nevertheless presumes to use with such show of confidence, of course does not know that Bright's disease is an affection of the circulatory system as well as of the kidney and that apoplexy is one of its frequent accompaniments and terminations. Blissfully unknowing of the long-recognized and very intimate relationship between Bright's disease and apoplexy, Mr. Weightman courageously entitles his little paragraph "Medical Science at Fault." A correspondent who, before writing, ascertains what he is writing about, would be of service to the *Tribune*, but some physicians would be deprived of their morning joke.

Precautions Against Cholera in London.

The outbreak of cholera on the continent of Europe has caused Dr. Williams, health officer to the port of London sanitary authorities, to issue an order that all vessels coming from ports infected or suspected to be infected with cholera be stopped at Gravesend and visited by a health officer. Every person on board is to be medically examined before being allowed to land, subject to furnishing name and address of destination. Then the health officers of the various districts to which the passengers are proceeding are notified and keep them under inspection during the incubation period of cholera. Three health officers are engaged in the work of boarding vessels at Gravesend. Persons found suffering from symptoms even suspicious of cholera are immediately removed to the port sanitary hospital at Denton and the vessel and all infected effects are thoroughly disinfected.

Medical News

CALIFORNIA.

Fires.—The Southern California State Hospital for the Insane, Patton, had a narrow escape from a disastrous fire September 15. Damage amounting to $2,000 was done.——The residence of Dr. David B. Fields, Weaverville, was destroyed by fire September 27.

New Hospital.—Early in October the new Santa Fe Hospital, Los Angeles, will be opened for use. It is probable that it will be used jointly by the Santa Fe, Southern Pacific and Salt Lake roads. The buildings are seven in number, connected with covered passages, and have cost altogether about $200,000.

Free Clinic Established.—On October 2 a free medical and surgical clinic was opened at the hospital, Los Angeles, which is under the charge of the Sisters of Charity of St. Vincent De Paul. The surgical department is under the direction of Drs. Ernest A. Bryant and E. T. Dillon. The heads of other departments will be announced later.

Vital Statistics.—During August, 1,844 deaths were reported in the state, of which 281 were due to tuberculosis, 194 to violence, 172 to heart disease, 114 to cancer, 90 to cerebral hemorrhage, and 89 to pneumonia. About 1 death in 7 was due to tuberculosis, 1 in 11 to heart disease, 1 in 20 to cerebral hemorrhage and pneumonia, and 1 in 25 to senility, nephritis and diarrhea.

Coroners Organized.—The coroners of the southern portion of California met at Los Angeles September 18 for organization. The object of the association is to bring about collective and organized action among the coroners in studying the rights, duties and privileges of coroners so as to have proper legislation passed, to have conflict on laws in coroners' duties cleared up and corrected, and to have defects in practice eliminated.

Personal.—Dr. John I. Stephen, San Francisco, chief surgeon of the Emergency Hospital service, has been deposed and Dr. Charles F. Miller has been appointed his successor.——Dr. John D. Dameron, superintendent of the San Joaquin Hospital, near French Camp, was stabbed in the back by a patient September 21, is paralyzed from the waist down and it is feared may not recover.——Dr. Herman E. Hassey, chief surgeon for eighteen years of the Soldiers' Home Hospital, Sawtelle, has resigned.——Dr. Robert C. Howe, sanitary inspector, San Francisco, suspended under charges of being absent without leave, has resigned.

COLORADO.

Sanitarium Dedicated.—The new Evangelical Lutheran Sanitarium for Tuberculosis, north of Denver, was dedicated with appropriate ceremonies September 10.

Death and Disease in August.—Seven hundred and ninety deaths were reported during August, equivalent to an annual rate per 1,000 of 13.92. Typhoid fever caused 28 deaths and diphtheria 4. During the month 248 cases of typhoid fever were reported, an increase of 18; 31 cases of smallpox, an increase of 18; 33 cases of scarlet fever, a decrease of 1, and 24 cases of diphtheria, a decrease of 13.

Personal.—Dr. and Mrs. Albert Atwood Blackman, Colorado Springs, sailed for Germany September 5.——Dr. Ella A. Mead has been appointed city physician of Greeley.——Dr. Orson B. Adams, Pueblo, has been appointed mine surgeon for the Colorado Fuel and Iron Company, with headquarters at Tercio.——Dr. Frank A. Washburn, Boulder, has sold his interest in the Place Sanitarium to Dr. Olney G. Place.

CONNECTICUT.

Epileptic Commission Appointed.—In July last the governor appointed Drs. Max Mailhouse, New Haven; Frank K. Hallock, Cromwell, and Edwin A. Down, Hartford, a commission to investigate plans and methods for the care and treatment of epileptics, to report at the session of the legislature in 1907.

Personal.—Dr. Walter G. Murphy, East Hartford, probation officer, has resigned.——Dr. Charles James Fox, Willimantic, has removed to Hartford and announces that he has limited his practice to diseases of the digestive tract and skin.——Dr. Anthony J. Hill, Torrington, has returned after a year in Ireland.

Bequests.—By the terms of the will of the late Mrs. Mary A. Stevens, Danbury, the bulk of her estate will eventually go to the Danbury Hospital for an addition to the institution, to be known as the Darius Stevens annex. There is a prospect, however, that the will may be contested.——Mrs. Edward R. Harkness, New London, has donated $1,000 to the Memorial Hospital, to be expended in the improvement of the sanitary equipment of the preparatory and operating rooms.

DELAWARE.

Cost of Typhoid.—In a letter prepared by the chief engineer of the water department of Wilmington, asking for an extraordinary appropriation to be used in the construction of a permanent filtration system for the city, he alleges that the annual loss to the community from typhoid fever exceeds $280,000.

Personal.—Dr. James A. Draper, Jr., has been elected a member of the surgical staff of the Delaware Hospital, Wilmington, vice Dr. Howard Ogle, deceased.——Drs. Albert Robin and Harold L. Springer have been elected pathologists and members of the staff of the Delaware Hospital.——Dr. Joseph H. Chandler, a lifelong resident of Centerville, has moved to Wilmington.

Donations for Hospital.—Mrs. Julia E. Gibbons and her daughter, Mrs. George A. Elliott, have presented $5,000 to the Delaware Hospital, Wilmington, to endow a memorial bed for the late Richard P. Gibbons.——Mrs. Alexis I. Dupont and her children have completed a laboratory for the hospital, and Mrs. Eugene Dupont has changed the Bush ward into a lecture room at her own expense.

DISTRICT OF COLUMBIA.

Transferred to the Government.—The tract of land near the district line, which has been selected as a site for the Army General Hospital, Washington, was formally transferred September 8. The consideration was $98,222.90.

Personal.—Dr. and Mrs. H. L. E. Johnson returned from a trip to the Pacific Coast, Alaska and Canada September 17.——Dr. Hirschel Baldwin has been appointed resident physician and superintendent of the Eastern Dispensary and Casualty Hospital, Washington.

GEORGIA.

Fire at Glennville.—A fire in Glennville September 27 destroyed the storehouse of Dr. F. R. Cross and the office of Dr. W. H. Mann.

Personal.—Dr. Maury M. Stapler, Macon, returned from Europe October 4.——Dr. Claude A. Smith, Atlanta, has been elected city bacteriologist and chemist, vice Dr. Henry F. Harris.——William E. Braswell, Loganville, has been given a beneficiary scholarship in the department of medicine of the University of Georgia, Augusta.

ILLINOIS.

School Closes.—The Emerson school of Bloomington has been closed on account of an epidemic of diphtheria.

New Hospital.—The contract for building the proposed Catholic Hospital at Taylorville has been let for $18,058. The hospital is to be completed on or before Feb. 1, 1906.

Typhoid at Pana.—An epidemic of typhoid is reported to be raging in the German settlement northeast of Pana. The infection is said to be due to the use of ice from an infected pond.

Releases Mortgage.—Matthias Schnell of Rock Island, who took a mortgage from the Sisters of St. Anthony's Hospital for $10,000 in 1904, entered release of the mortgage September 25.

Physician Wins Suit.—In the case of Katie Helen against Dr. T. J. McKinney, Gifford, in which damages to the extent of $5,000 were claimed by the plaintiff for malpractice, the jury found for the defendant.

Hospital Plan Rejected.—At a meeting of the Fairhope Improvement Association October 3 in Oak Park, a resolution was adopted to block further progress of the Oak Park Hospital Association toward accepting the offer submitted by Dr. J. W. Tope to buy the property and turn it over to Catholic sisters for a hospital.

Personal.—Dr. W. L. Wylie, Sparta, has returned from a visit to Colorado.——Dr. B. C. Green, Keithsburg, is convalescing from injuries received some weeks ago by being thrown from a fractious horse.——Dr. J. H. Porter, Clinton, was operated on September 28 in Chicago for cholelithiasis.——Dr. J. W. Morgan, Moline, has returned to the city after a year in the Southwest.——Dr. H. W. Wayles, Lennock, is reported to be failing rapidly in Pennsylvania, where he is a patient.——Dr. E. C. Aeley, Quincy, has returned from Portland, Ore.——Dr. Martin W. Cushing, Joliet, had a slight cerebral hemorrhage October 4.

Chicago.

Annual Gynecological Society Meeting.—The twenty-seventh annual meeting will be held at the Auditorium Annex, October 20, at 8 p. m. The business meeting and election of officers will be followed by the banquet.

Personal.—Dr. N. Ellis Oliver has gone to England for a trip of six weeks.——Dr. J. R. Lynch was robbed of his watch by holdup men September 30.——Dr. and Mrs. Cole, Englewood, will soon leave for Los Angeles for the winter.

New Hospital Planned.—The directors of the Chicago Lying-in Hospital are planning the erection of a new hospital to cost $250,000 as the present quarters are entirely inadequate. The proposed new hospital will have accommodations for about seventy patients and will possess facilities for handling cases from all grades of society, the main object being to establish a place where wives of the wage earners can be cared for at slight expense.

Months of Low Death Rate.—October and November are the two months of lowest death rates in Chicago, and October has opened with satisfactory promise. For the week ended October 7 the death rate was at the annual rate of 12.36 per 1,000, which is considerably lower than the average October rate for the decade 1895-1904, which was 13.16 per 1,000. Of the total deaths reported the indicated decreases as compared with the previous week are: Typhoid fever, suicide and whooping cough, each 3; diphtheria, 4; apoplexy and tuberculosis, each 5, and acute intestinal disease, 8.

The Summer Mortality.—During the summer of 1905, which ended September 23, 6,889 deaths occurred, or 794 more than in the summer of 1904, the respective annual death rates per 1,000 being 13.24 and 12.24. Of children under 1 year, 1,837 died in 1905 and 1,478 in 1904; of children between 1 and 5, 717 in 1905 and 522 in 1904; and of individuals over 60 years, 1,117 died in 1905 an 1,058 in 1904. The most important causes of death were: Acute intestinal diseases, consumption, 732; violence, including suicide, 599; heart diseases, 521; Bright's disease, 472; pneumonia, 383; and cancer, 311.

INDIANA.

New Sanitarium.—A site has been purchased in Princeton, on which a sanitarium is to be erected, to cost $20,000. Drs. Franklin Blair, A. Ziliak and Robert S. Anderson are the promoters of the enterprise.

Illegal Practitioner Fined.—Gilbert Williams, charged with practicing medicine without a license in Evansville, was fined $20 and costs September 22. He says he will appeal the case. He has been practicing with his brother under the firm name of "the Dr. Bert Company."

Physician Goes to Prison.—Dr. Charles L. Landfair, Bluffton, sentenced to the penitentiary for a term of from three to fourteen years and to pay a fine of $100 for criminal malpractice, was taken to the Indiana northern penitentiary, Michigan City, September 23.

Personal.—Dr. Charles C. Morris, Rockville, has taken a trip to Portland, Ore.——Dr. Sherman B. Hitt, Greensburg, was the lucky holder of a ticket entitling him to a $600 automobile at the drawing held September 25.——Dr. John P. Salb, Jasper, has been appointed division surgeon for the Southern Railway.——Dr. Albert E. Powell, Marion, is in a serious condition since his return from Toledo, where he underwent operation.

IOWA.

Raises Fee for Itinerants.—Dubuque has raised the license fee for traveling doctors to $5 a day, or $150 a month.

The Last of Kraus.—The notorious itinerant, who calls himself "Phenomenal Kraus," and his associates, have agreed to abandon Des Moines and Polk County as a field for the sale of their nostrums and their alleged miraculous cures, provided the cases pending against them be dropped. They agree to pay all costs incurred.

Law Defense Company.—A corporation—the Law Defense Company—has recently been incorporated with a capital of $100,000, whose object is to protect doctors, lawyers and dentists against damage suits, as well as individuals and corportations against various kinds of legal prosecutions. Only the expense and trouble of litigation, not judgments and damages, are to be insured against.

Washington County Medical Society.—The annual meeting of this society was held September 19. The program included papers on "Chylous Ascites," "Appendicitis," "Artificial Feeding of Infants" and "Pneumonia." In the evening a public lecture was given on "Food and Drug Adulterations." The following officers were elected for the ensuing year: President, Dr. William H. McCaw, Winfield; vice-president, Dr. Emmett T. Wickham, Washington; secretary, Dr. Clyde A. Boice, Washington (re-elected).

MARYLAND.

Personal.—Prof. Hans Horst Meyer, the Herter lecturer at the Johns Hopkins University, with his two sons, was the guest of Prof. J. J. Abell during his stay in Baltimore last week.——Dr. S. Suzuki of the Imperial Japanese navy was the guest of Dr. William S. Halstead at Baltimore October 7, and inspected the Naval Academy at Annapolis on October 8.——Prof. Harry Friedenwald delivered the opening address at the College of Physicians and Surgeons, the evening of October 3.

Diphtheria.—The epidemic of diphtheria at the Naval Academy, Annapolis, is abating. Between 40 and 50 of the midshipmen are still receiving treatment at the hospital, but there have been no new cases for several days. The midshipmen are improving as well as the two marine officers at the Marine Barracks, and a young child of one of the naval officers. The quarantine restrictions placed in force by Rear Admiral Sands will not be raised until a few days before October 16.

Health Report.—The health report of Baltimore for September shows 813 deaths and but 800 births, 293 (36.04 per cent.) of the former occurring in children under 5 years. Some singular contrasts are seen, viz., while 327 white males and 282 white females died, the corresponding numbers among the colored were 94 and 110; again, of the births there were 303 white males, 340 white females, 78 colored males and 79 colored females. There were 198 cases of typhoid reported and 79 cases of tuberculosis. The figures for September, 1904, being, respectively, 128 and 47. Measles, whooping cough and pneumonia are on the increase.

MASSACHUSETTS.

Changes at Harvard.—*Dr. Chauncy Williams Norton has resigned as assistant in anatomy at the Harvard Medical School.* Franz Pfaff, M.D., has been appointed professor of pharmacology and therapeutics. The administrative board for 1905-1906 will be: William Lambert Richardson, dean; John Collins Warren, Frederick Cheever Shattuck, William Fiske Whitney, Charles Montraville Green, Charles Harrington, Frany Burr Mallory, Walter Bradford Cannon and John Warren.

Springfield's Typhoid.—Springfield has been having an epidemic of typhoid fever. About 140 cases have occurred since August 1. Dr. George B. Magrath was sent as an expert from Boston by the State Board of Health, and his investigations make it probable that the street venders and push-cart peddlers of fruits, vegetables and other food materials are responsible for the spread of the disease. For the earliest cases occurred in their families and the local board of health has found a condition of great filth on the two streets where most of them live.

MICHIGAN.

City Accepts Hospital.—The city council of Flint has formally accepted the bequest of $25,000 and a tract of land left to the city by the late James J. Hurley for a public hospital.

Sanitarium Organized.—The Marine City Sanitarium was organized September 23 with a capital stock of $60,000. Dr. Robert B. Baird was elected president of the board of directors.

Off to Prison.—Dr. Scott F. Hodge, Detroit, convicted of manslaughter in connection with the death of Anna Lehman, in an attempt to produce abortion, was taken to the state penitentiary at Ionia September 22 to serve an indeterminate term of imprisonment of six to nine years.

Question of License.—W. H. Griswold, Battle Creek, charged with practicing medicine without a license, who in his appeal claimed that as he had been in practice prior to the enactment of the amendment of the law of 1903 he was not obliged to take out a license, was non-suited by the Supreme Court September 22.

Dr. Hull's Will.—The will of the late Dr. Harry D. Hull, Adrian, provides for a $3,000 lavatory, and creates a fund to keep in repair neglected monuments and markers in Oakwoods Cemetery. A provision in the will also directs that all accounts against patients, except those which would go to offset creditors' accounts, be marked off his books.

Medical Reading Room Opened.—A special reading room for physicians, nurses and medical students was opened at the Ryerson Library, Grand Rapids, September 25. In this room there are between 30 and 40 medical periodicals from America and abroad, and a collection of more than 4,000 volumes transferred by the old medical library association. The physicians of Grand Rapids have agreed to contribute to the library not less than $50 a year for medical periodicals for a period of five years.

MINNESOTA.

New Hospital.—The new hospital at Luverne will be ready for occupancy early this month.

College Opens.—The eighteenth annual session of the College of Medicine and Surgery, University of Minnesota, Minneapolis, opened September 19. Dr. Arthur Sweeney, St. Paul, delivered the opening address on "Ideals in Medicine."

Physiciain Acquitted.—Dr. Malcolm McKinnon, Fosston, who was charged with criminal assault, was discharged at his preliminary examination, the defense showing that the complaining witness was in a state of hysteria and was wholly irresponsible.

Plan Postgraduate Work.—At a meeting of the St. Louis County Medical Society at Duluth a plan was discussed to form a medical study academy to take up postgraduate subjects. It is proposed to include the practitioners of Superior and the Iron Range in this work.

The Afflicted.—"Dr." Michael Mitchell, who was in trouble with the authorities of Washington County on account of practicing medicine without a license, died insane at the Stillwater Hospital September 17.——Dr. Edward J. Clark, Minneapolis, while shooting near Rush City, received a heavy charge of birdshot in the palm of the left hand by the accidental discharge of a gun, and will be deprived of the use of the hand for a considerable time, if not permanently.

Personal.—Dr. John B. Town, Hibbing, has resigned from his position on the staff of the Rood Hospital and will practice in Topeka, Kan.——Dr. George Crossette, Minneapolis, has taken a position on the staff of the Rood Hospital, Hibbing.——Dr. Harry K. Reed, Minneapolis, will soon remove to Hibbing and associate himself with the Rood Hospital.——Dr. Alexander H. Dunlap, Crookston, has been appointed physician of Polk County.——Dr. E. W. Gagg has been appointed physician of Breckenridge, vice Dr. L. W. Armstrong, resigned.——Dr. Ernest A. Woods, Clear Lake, has moved to California.

MISSOURI.

College Opens.—Ensworth-Central Medical College, St. Joseph, opened for its annual session September 19. Mr. George L. Zwick delivered the address of the evening.

Appropriation for Quarantine Hospital.—The House of Delegates, October 3, passed a council bill appropriating $75,000 for the construction of a municipal quarantine hospital south of St. Louis.

Illegal Practitioner in Jail.—"Dr." J. T. Davis, Harrisonville, was arrested at Pleasant Hill October 3 for practicing medicine without a license. He was unable to pay his fine of $50 and costs and is now serving his time in the county jail.

Hospital Employes Poisoned.—Nearly 100 employes of the St. Louis City Hospital, doctors, nurses, attendants and clerks, were taken violently ill with ptomain poisoning September 30, due, it is supposed, to infected milk or oysters. All, however, recovered.

Cost of City Hospital.—The cost of the new city hospital at St. Louis up to date is stated to have been $657,732.72, divided as follows: Past construction, $573,991.62; pathologic building, $39,046; fence, $4,910.10; administration building, $34.-785, and grading, $5,000.

Typhoid at State University.—After investigating the typhoid fever situation at Columbia, the State Board of Health issued a statement that there was no occasion for alarm among students and commending the action of the city authorities in the campaign for sanitation.

Small Proportion of Claim Allowed.—In the suit of Dr. David S. Booth, St. Louis, against the estate of the late Dr. Washington West, in which a claim of $10,000 was made for professional service rendered to Dr. West and to a guest of his, the probate judge allowed settlement for $750 September 14.

Personal.—Dr. Charles E. Gimbel, St. Louis, has been committed to the insane department of the County Hospital, Denver.——Dr. Frank Riley, St. Joseph, suffered a cerebral hemorrhage September 25.——Mrs. Edward C. Runge, widow of the late Dr. Runge, has been appointed librarian of the St. Louis Medical College, and has been put in charge of the co-operative store at the college.

Buchanan County's Insane.—Dr. Charles R. Woodson, superintendent of State Hospital No. 2, St. Joseph, who is charged with using county funds for state purposes and with charging Buchanan County excessive rates for the support of patients, and who on September 11 demanded immediate payment of bills due the hospital from the county, declaring that unless the bills were paid by 11 a. m., September 12, he would turn the 200 indigent insane from the county out of the hospital, received a warrant on that date from the county for $12,-233.80, which, on presentation to the county treasurer, was returned stamped "not paid for lack of funds." The warrant was accordingly sent to protest.

NEW JERSEY.

Finding Adulterated Milk.—Much adulterated milk is being found by the pure food inspectors in their work in different parts of the state. Their last monthly report shows that 437 specimens were collected, of which 121 were found to be adulterated. Out of 32 samples of cream 8 showed adulterations.

NEW YORK.

Personal.—Burglars entered the home of Dr. J. Carl Schmuck at Lawrence, L. I., on October 3 and carried away silverware and valuables worth about $2,000.

The Work of Consolidation.—Dr. Joseph D. Bryant, president of the Medical Society of the State of New York, and Dr. J. Riddle Goffe, president of the New York State Medical Association, have each sent letters to the members of the respective bodies, stating that after consolidation of the Medical Society of the State of New York with the New York State Medical Association all members of the consolidated body in good standing will be entitled to vote on the question of the Principles of Medical Ethics of the American Medical Association when ordered by the court, as provided in section 7, which states that it is covenanted and agreed by the parties hereto that as soon as practicable after the entry of an order for the consolidation of the corporations the following proposition shall be submitted by referendum to the vote of the members of the society, namely: "The Principles of Medical Ethics of the American Medical Association being suggestive and advisory, shall be the guide of members in their relations to each other and to the public." A copy of the Principles of Medical Ethics, adopted unanimously at the annual session of the American Medical Association, held in New Orelans, was enclosed with the letter.

State's Mortality Higher.—The State Department of Health reports that the mortality of the state in August exceeded by 1,000 the average mortality for that month in the last seven years, which is 10,800. The July mortality exceeded the average by 1,300. This large increase was due to local diseases and general diseases which are not epidemic. There was a considerable increase in the number of deaths from whooping cough and typhoid fever. Since the first of January there had been 60,000 cases of typhoid fever in this state, with 500 deaths from this cause alone in Greater New York. This is attributed to the increased volume of sewage pouring into the streams of the state. It will be the fixed policy of the state health department hereafter not to grant any permits to discharge sewage into public waters, except where imperatively necessary. It was thought that summer resorts were polluting the lakes and streams and a systematic investigation of these resorts would be made. Of the total number of deaths for the month of August, 1,090 were from consumption, 10 per cent. of the whole number. The report urges the registration of all consumptives with the local health boards. It is noteworthy that while the urban mortality was 1,200 less in August than in July, the deaths in rural towns were increased by almost 10 per cent., and their diarrheal mortality was increased by 60 per cent. from that of July.

New York City.

Fewer Medical Students.—The registration in the School of Medicine of Columbia University shows a falling off from last year, there being a decrease of 107 in the number of matriculates.

Personal.—Dr. and Mrs. William T. Bull will sail for Europe on October 10.——Dr. and Mrs. John G. Perry sailed for Europe on the *Koenig Albert* on October 5.——Dr. A. J. McCosh arrived on the *Kaiser Wilhelm* on October 3.

Low Death Rate for City.—The weekly figures of mortality show that in the week ended September 30 the death rate was lower than ever before for that time of year. The rate was 15.75 per 1,000, as against 17.14 for the corresponding week of 1904. In the borough of Richmond there were only 10 deaths.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended September 30, 380 cases of tuberculosis, with 146 deaths; 171 cases of diphtheria and croup, with 18 deaths; 113 cases of typhoid, with 24 deaths; 73 cases of measles, with 2 deaths; 51 cases of scarlet fever, with 5 deaths; 2 cases of cerebrospinal meningitis, with 5 deaths, and 23 cases of varicella.

Fresh Air Season Ends.—The New York Association for Improving the Condition of the Poor reports that during the season which closed October 4, 3,900 women and children have had ten days on the beach, 15,500 enjoyed day excursions, and 165 sick wage earners were boarded in the country for two weeks or more. The work for tuberculous crippled children will be continued through the winter, $30,000 having already been offered toward the permanent hospital.

New Laboratory.—The capacity of the New York University Medical School, which opened October 4, has been greatly increased by the completion of the new laboratory, which is six stories in height and adjoins the college building. This made it possible to admit an unexpectedly large freshman class this year. More than 1,000,000 cases were treated last year in the clinic connected with the college, and this building will also permit of the extension of this work.

Danger in Brooklyn Water.—The Health Department has published a statement regarding the results of the analysis of samples of Brooklyn waters which show the presence of the colon bacilli. The report states that the dangers of the situation are not so much in present conditions as in the fact that they are forerunners of serious conditions which may obtain at any time. Sand filtration is the remedy suggested, and until this can be effected home filtration and boiling are recommended.

Unclean Bakeries.—Announcement has been made that the Board of Health, in connection with a delegation of the Central Federated Union, had inspected forty-two bakeries in Manhattan and that a large majority of them were found in an unsanitary condition. The health commissioner stated that he had made plans to have every bakery in Greater New York inspected and those that were found insanitary would have to comply with the law. It is alleged that out of 2,000 bakeries in New York 400 are in an insanitary condition. The inspectors have found no bakers suffering from tuberculosis so far.

Board of Health Wants More Money.—The day before Dr. Darlington appeared before the board of estimate to ask for an appropriation of $2,516,396, as against $1,685,077 allowed last year, he sent a special delivery letter to each member of the board of estimate explaining the urgent necessity for the increase that he asked. The additional funds were not asked for the purpose of increasing any salaries, but for medical school inspection. Dr. Darlington met some opposition in the person of Comptroller Grout, who claimed that the department was trying to do more work than the law required, and that they did not have authority to go into all the schools and examine the children.

Summer Milk Depots Closed.—Most of the Nathan Straus pasteurized milk depots have been closed for the season. The maximum capacity of the laboratory was reached this summer, and the necessity for enlarged facilities for the immediate future is apparent. So far this year there have been 2,668,397 bottles of milk dispensed, as against 2,149,194 for the previous year. The Health Department statistics show that the death rate among children under 5 years of age in 1890, previous to the use of pasteurized milk by the poor, was 96 per 1,000, while for the year 1904 the rate was 63 per 1,000. A movement is on foot to have the work of supplying pasteurized milk so extended as to include practically the entire supply of the infant population. It is expected that the city or state will shortly take up the question.

Report of Health Department.—The report from the Health Department for the first six months of 1905 shows that the number of inspections made by officers of the sanitary bureau was 999,658, against 799,161 in 1904; 8,668 nuisances were abated by personal effort of the inspectors. Under the child labor law, which assigns to the department of health the issuance of certificates permitting the employment of children between the ages of 14 and 16, 6,700 certificates were issued and about 2,000 applications rejected. Thirteen thousand mercantile establishments have been inspected. There was a diminution in the number of contagious diseases reported, 17,456 being reported, as against 39,114 for the corresponding period of the previous year. The report estimates that 25 per cent. of the children in the schools are suffering from morbid conditions that interfere with their development. Although the work of inspecting the schools is very rigid, only 10,585 children were excluded from the schools between January and July, as opposed to 51,644 who were excluded in the first months of 1903. The death rate for the first six months of 1905 was 19.03 per 1,000, as against 22.24 in the previous year. This death rate corrected on the recent population of New York would be only a little over 17. The report emphasizes the necessity of preventing expectoration in public places, and recommends that inspectors be better paid.

OHIO.

College Opens.—The Cleveland College of Physicians and Surgeons opened September 20.——Dr. Milton J. Lichty delivered the address of the evening.

Physician Acquitted.—Dr. Lucien W. McKinley, Columbus, bound over to the grand jury for causing, as alleged, the death of Carrie Bennett, by an illegal operation, was not indicted by the grand jury.

Tuberculosis Clinic a Success.—The clinic for tuberculosis recently opened at Cleveland has proven to be so popular that at present more than 60 patients are under treatment and it seems probable that branches must be opened in various parts of the city to provide for those applying for treatment.

Objects to Advertising.—At a meeting of the Ottawa County Medical Society September 13 a resolution was adopted that the names of attending physicians be omitted from all newspaper reports of injuries or sickness, because of incorrect and often exaggerated reports in the newspapers and because it is considered contrary to medical ethics for physicians to advertise.

Hospital Staff Changes.—At a special meeting of the medical and surgical staff of the Mahoning Valley Hospital at Youngstown, September 26, Dr. Howard B. Hills was elected president to succeed the late Dr. Jared E. Cohen; Dr. William E. Ranz was elected head of the surgical staff and Dr. Elmer W. Coe, assistant. Dr. John MacCurdy was elected vice-president; Dr. Thomas J. Arundel, secretary, and Dr. Howard B. Hills, chairman of the training school committee.

Right of Way for Toledo Physicians.—Dr. A. D. Hobart, Toledo, Ohio, during his last weeks in the city council, framed and had passed an ordinance "granting to physicians and ambulances the right of way in the city of Toledo, Ohio." The badges, selected by a committee of the Academy of Medicine of Toledo and Lucas County, with the approval of the city clerk, have arrived and are being purchased by the physicians who drive carriages. This is the first ordinance in Toledo for the protection of the medical profession of the city.

Condemns Water Supply.—At the meeting of Lake County Medical Society, Paynesville, Dr. William T. Miller, Cleveland, member of the State Board of Health, read a paper on "Water Filtration," with particular reference to the conditions which obtained at Paynesville. He declared that the outlet of sewage system of Cleveland was only about seventeen miles from the place from which Paynesville obtains its supply of drinking water and that within three hours the sewage of Cleveland would at times reach Paynesville. The members of the society were unanimous in condemning the present plan of emptying waste matter either into the river or the lake.

Personal.—Dr. Martin L. Williams, Warren, is seriously ill with pneumonia.——Dr. William J. Taylor, East Liverpool, has resigned as city physician.——Dr. and Mrs. George F. Brubaker, Springfield, returned this month from an extended stay in California and the West.——Dr. and Mrs. Bryant M. Tower, Conneaut, have returned from Colorado Springs.——Dr. Charles S. Green, Fostoria, was thrown from his buggy in a runaway accident and sustained a fractured rib and severe cuts and contusions.——Dr. Jerome Bland, Bucyrus, who has been seriously ill for a long time, is now convalescent.——Dr. B. Decatur Smith, Cincinnati, has been appointed surgeon for the C., H. & D. R. R., Pere Marquette System and C., C. & L. R. R.——Dr. Leo Danziger, Cincinnati, is critically ill at the Deaconess Hospital.——Dr. and Mrs. E. Luther Trimmer, East Liverpool, have moved to San Luis Obispo, Cal.——Dr. James H. Lowe and family, Piqua, who have been making a trip through the West, returned September 25.——Dr. William H. Booth, Salem, is making a good recovery from typhoid fever.——Dr. Orville A. Rhoads and family, Salem, expect to leave soon for a winter's trip to the Pacific Coast and the South.——Dr. Marion Squire, Randolph, sustained severe bruises in a runaway accident at Ravenna, September 28.

OREGON.

Personal.—Dr. F. Cauthorn has been appointed city physician of Portland.

Pays Dividend on Subscription.—The committee of arrangements of the Portland session of the American Medical Association has returned to its subscribers a dividend of 51 per cent.

College Opened.—The medical department of the Oregon State University, Portland, opened September 17. Dr. Simeon E. Josephi delivered the opening address. Dr. O. P. Wright has succeeded the late Dr. Alexander D. McKenzie as lecturer on clinical medicine; Mr. W. L. Brewster succeeds Mr. Fenton as lecturer on medical jurisprudence; Drs. L. H. Hamilton and Frank M. Taylor have been added to the faculty as lecturers on electro-therapeutics and demonstrators of electricity and *x*-ray therapeutics, and Dr. George S. Whiteside has been appointed lecturer on genitourinary and skin diseases.

PENNSYLVANIA.

Money for Hospital.—The Lancaster General Hospital was the recipient of a gift of $10,000 from Mrs. Mary L. Bear to endow a bed to the memory of her husband, Reuben F. Bear, deceased.

Philadelphia.

Charity Hospital Report.—In Charity Hospital during September 1,062 patients were treated and 754 prescriptions compounded.

New Ambulance for Samaritan Hospital.—The Women's Samaritan Club of Tioga, by a series of enterprises, secured funds sufficient to purchase the new ambulance for the Samaritan Hospital. The ambulance was presented by the club October 2.

To Enlarge Hospital.—Efforts are being made by the officials of the American Hospital for Diseases of the Stomach to enlarge the institution considerably. The present building accommodates 30 patients, but by the establishment of the present plan of enlargement many more can be cared for. The staff of the institution is composed of Drs. John B. Deaver, Lewis Brinton, John B. Shober, Sherbourne W. Dougherty, James Thorington and Ludwig Loeb.

Health Report.—The deaths reported last week numbered 404. This is an increase of 20 over the number reported the previous week, and an increase of 20 over the number reported in the corresponding period of last year. The principal causes of death were: Typhoid fever, 16; whooping cough, 7; diphtheria, 7; pulmonary tuberculosis, 39; cancer, 16; apoplexy, 22; heart disease, 63; acute respiratory disease, 21; enteritis (under 2 years), 35; enteritis (over 2 years), 7; Bright's disease, 30; accidents, 22; marasmus, 12. There were 191 cases of contagious disease reported, with 28 deaths, as compared with 161 cases and 18 deaths for the previous week. The new contagious diseases reported were as follows: Diphtheria, 70; scarlet fever, 29; typhoid fever, 92.

TEXAS.

Typhoid in Krum.—More than 40 cases of typhoid have developed in Krum during the last six weeks, and 6 deaths have occurred.

Damage by Fire.—In a fire at Houston September 18 the residence of Dr. Jacob H. Sampson was burned to the ground, the loss being $10,000, on which an insurance of $8,000 was carried.

Hospital for Houston.—George H. Hermann of Houston has given a block of land and $20,000 in cash for the establishment of a charity hospital in the city. Mrs. E. N. Gray and Mrs. T. W. House are soliciting the donation of an additional $20,000, which, with the amount already received, will be sufficient to erect and equip the institution. Three thousand dollars have already been secured toward the $20,000 required.

College News.—The building committee of the Fort Worth Medical University is preparing plans for the new college building to be erected at a cost of about $50,000. The sessions for the fall term, which opens this week, will be held in the old building.——The medical department of the University of Texas opened for its annual session October 2.——The new building for the Southwestern University Medical College, Dallas, was formally dedicated at the opening of the college year, October 3.

To Inspect School Children.—The president of the Dallas school board has appointed the following physicians as medical inspectors of schools to serve for one year: Drs. Scurry L. Terrell, W. E. Howard, Robert S. Yancey, Edward H. Cary, Theo. L. E. Arnold and Martin E. Taber. He has also appointed an advisory board consisting of Drs. John B. Smoot, J. Wilbur Bourland and T. M. Hackler. The inauguration of the work will be under the supervision of Dr. Frank J. Hall of the school board.

Personal.—Dr. Thomas W. Crowder, Sherman, was painfully burned in the right hand and arm while extinguishing a fire in his house September 4.——Dr. Edwin B. Smyth, Mart, was fined $100 in the county court September 15 for false imprisonment, the prosecution growing out of an arrest made on Dr. Smyth's order while he was serving as a judge at the election of high school trustees.——Dr. Benjamin M. Worsham, Austin, superintendent of the State Lunatic Asylum, is ill with appendicitis and an operation will probably be necessary.

VERMONT.

State Society Meeting.—The annual meeting of the Vermont Medical Society was held at the new college building, Burlington, October 12 and 13.

Gives State a Sanatorium.—Senator Redfield Proctor of Vermont, in a letter to Dr. William N. Bryant, Ludlow, secretary of the Vermont State Tuberculosis Commission, states that he will purchase a site for a state sanatorium for the treatment of incipient tuberculosis, erect a building to the cost of about $50,000, and endow it with $10,000, and as soon as the site is obtained will formally transfer it to the state board and will pay over the endowment fund as soon as the organization is ready to receive and invest it.

Personal.—Dr. W. T. Slayton has been appointed health officer for the town of Morristown and the village of Morrisville, vice Dr. C. C. Rublee, deceased.——Drs. F. S. Arnold and Marshall C. Twitchell have been appointed to the staff of the Fannie Allen Hospital, Burlington, in the eye, ear and throat department.——Dr. Clayton G. Andrews, Waterbury, for six years first assistant physician of the State Hospital for the Insane, has resigned, to take effect September 30.——Dr. Don D. Grout, Waterbury, has been elected superintendent of the State Hospital for the Insane, vice Dr. Marcello Hutchinson, resigned.——Dr. G. Carlton Berkley has been elected president, and Dr. John Gibson, secretary, of the St. Albans Hospital medical board.——Dr. Waldo J. Upton, Waterbury, has been appointed assistant superintendent of the State Hospital for the Insane.

VIRGINIA.

State Society Meets.—The twenty-sixth annual session of the Medical Society of Virginia will be held in the Y. M. C. A. building, Norfolk, October 24-27, under the presidency of Dr. William S. Christian, Urbana.

Personal.—Dr. John F. Winn has been appointed professor of obstetrics in University College of Medicine, Richmond.——Dr. John P. Davidson, Richmond, has returned from England.——Dr. McM. Monroe Moran, Pinner's Point, has been appointed surgeon to the Atlantic Coast Line Railway.

Colleges Opened.—The Medical College of Virginia, Richmond, opened for its annual session September 26. Dr. Christopher Tompkins delivered the opening address.——The University College of Medicine, Richmond, formally opened for the year September 26. Dr. G. Paul La Roque, the new instructor in practical surgery at the college, has moved from Kingston, N. C., to Richmond.

WISCONSIN.

Pleads Guilty.—"Dr." Anna Regha, Kenosha, was arraigned in the circuit court, Racine, September 18, on the charge of committing a criminal operation and of conspiring to have a patient leave the state. She pleaded guilty to both charges and was fined $600 and costs.

College Opened.—The Wisconsin College of Physicians and Surgeons opened its thirteenth year September 19. The introductory lecture was given by Dr. Albert W. Myers. Dr. V. H. Bassett has been appointed professor of histology and pathology, with Dr. Newton Wason as his assistant. Drs. G. Frederick Shimmonek and Arthur Ritman have also been added to the faculty.

Personal.—Dr. Otto H. Forster has been appointed dermatologist to the Milwaukee Children's Free Hospital, vice Dr. Louis F. Frank, placed on the consulting staff. Dr. F. E. Walbridge has also been transferred to the consulting staff.——Dr. Hugo Philer, Waukesha, has been elected surgeon-general of the Grand Army of the Republic.——Dr. Friend C. Suiter, La Crosse, was robbed of a wallet containing $600 and valuable papers at the County Fair grounds, West Salem, September 7.——Dr. James T. Reeve, Appleton, completed the semi-centennial of his professional life September 3.—— Dr. Moses J. White, Milwaukee, superintendent of the County Hospital for the Insane, has returned from Portland, Ore.——Capt. Edgar C. Barnes, M.D., Ripon, has been appointed major-surgeon of the Second Infantry, W. N. G., vice Major F. C. Moulding, Watertown, resigned.——Dr. Thomas R. Hastings, Lime Ridge, has returned from a visit to Utah.——Dr. August F. Schoen, Mayville, has returned from Europe.

GENERAL.

American Academy of Medicine.—The thirtieth annual meeting will be held in Chicago Nov. 9-10, 1905. Committees will report on medical practice acts, teaching of hygiene in the public schools, and the collegiate degrees. The program includes the following papers: "Altruism in the Medical Profession," being the annual president's address, by Dr. Winfield S. Hall, Chicago; "Maturation and Senility," by Dr. A. L. Benedict, Buffalo; "The Medical Features of the *Papyrus Ebers*," by Dr. Carl von Klein, Chicago, and a symposium on "The Influence of Recreation on the Individual and the Community from Medical and Sociologic Standpoints," in which series the following papers are promised: "The Physiology of Recreation," by Dr. G. W. McCaskey, Fort Wayne, Ind.; "Recreation in Its Influence on the Nervous System," by Dr. W. J. Herdman, Ann Arbor, Mich.; "The Ceremonial and Festa in the Organized Recreation of Larger Groups of Individuals," by Dr. Bayard Holmes, Chicago; "The Relation of Recreation to Education," by Prof. Robert K. Row, Berwyn, Ill. Not only physicians but others interested will be welcome at the open sessions, which are to be held November 9 at 11 a. m., committee reports and discussion; at 8 p. m., president's address; and November 10 at 10:30 a. m., the other papers above mentioned and discussion thereon.

Cholera in Manila.—Several cases of cholera have been reported in Manila from various parts of the city and Bilibid prison. The source of the infection is being investigated, and the board of health is doing everything possible to control the situation. Outgoing quarantine has been imposed on all vessels leaving Manila for other ports in the islands or in the United States.

Health of Cuba.—Acting Assistant Surgeon Delgado of the Public Health and Marine-Hospital Service reports that there are still many cases of dengue in Havana and a few cases of typhoid, but no pernicious anemia. There are no yellow fever cases or suspects in the city. The epidemic of dengue which prevailed in Havana has spread to Matanzas and is spreading to every section of that town.

Harvey Society Lectures.—The Harvey Society of New York, described by its constitution as "a society for the diffusion of the knowledge of the medical sciences," offers the following course of lectures, to be given under the patronage of the New York Academy of Medicine:

Oct. 14 .Prof. Carl von Noorden, "Modern Problems of Metabolism."
Nov. 4. Prof. F. G. Novy, "Trypanosomes."
Nov. 18. Dr. P. A. Levene, "Autolysis."
Jan. 20. Prof. W. H. Park, "A Critical Study of Serum Therapy."
Jan. 27. Prof. Lewellys F. Barker, "The Neurones."
Feb. 2. Prof. F. S. Lee, "Fatigue."
Feb. 9. Prof. L. B. Mendel, "The Formation of Uric Acid."
Feb. 16. Prof. T. H. Morgan, "The Extent and Limitations of the Power to Regenerate in Man and Other Vertebrates."
Feb. 23. Prof. Charles S. Minot, "The Nature and Cause of Old Age."
March 2. Prof. J. C. Webbster, "Modern Views Regarding Placentation."
March 9. Prof. Theobald Smith, "Some phases of Tuberculosis."
March 16. Prof. W. H. Howell, "The Cause of the Heart Beat."

The lectures will be given in the Academy of Medicine at half-past 8 on the above Saturday evenings.

Less Yellow Fever.—The general improvement continues. In the week ending October 7 there were in New Orleans 176 new cases and 22 deaths, as against 183 cases and 23 deaths in the previous week. The New Orleans hotels begin to fill with visitors. It is expected by the end of this week many quarantines will be modified and that all will be raised by November 1. There has been a slight spread of the epidemic in Mississippi, but on the whole there is good control, and not so many new cases at Natchez and Vicksburg. At Hamburg the situation has been bad. Alabama quarantined against the whole state of Mississippi. There has been a sharp war of words concerning quarantine on the Mississippi-Arkansas boundary between Dr. Hunter of the former state and Dr. Runyan of the new Arkansas Board of Health.——Dr. D. C. Anderson, who had been sent to Tallulah, La., by the State Board of Health, died of yellow fever.——The new Arkansas Board of Health, through its president, Dr. Runyan, has issued an order that no Florida oranges or other fruit shall be unloaded in Arkansas. As a result the Florida papers are hurling jibes at Dr. Runyan, because the yellow fever in Florida, at Pensacola, is as far from the orange groves—500 to 700 miles—as is Arkansas itself, and also because no one has yet suggested that oranges carry mosquitoes.——The United States Public Health and Marine-Hospital Service has circulated a note on the history and habits of the mosquito, by Prof. L. O. Howard, chief entomologist of the Department of Agriculture. In this it is noted that late in the summer the stegomyia may be carried well to the North by train and boat.——Mexico is nearly free from yellow fever.——The official reports of the United States Public Health and Marine-Hospital Service show that many refugees came North from the infected Mississippi towns about October 1, the larger portion coming to Chicago and numbering nearly or quite 200 persons.——It has developed clearly that most of the towns along the line of the Yazoo & Mississippi Valley Railway are infected and that the infection dates from a cheap excursion into New Orleans which was run by that railroad in July, just before yellow fever was admitted to be present in New Orleans. Of course, it follows that the early cases for several successive crops either were unrecognized or concealed. For instance, at Port Gibson two cases were admitted September 29, but investigation showed that probably 50 prior cases had not been reported. Even yet not all the physicians at Vicksburg will report their cases, and a portion of the populace fumigates in only a perfunctory way. In consequence it is difficult to make real progress there.——The little town of New Iberia, La., boasts of its rational methods and of their complete success. With $3,000 from the city treasury and $2,000 from citizens, the town from the beginning of the epidemic has been thoroughly guarded without shotguns and has been repeatedy inspected by districts. It had its detention camps and its screened hospital. The Southern Pacific Railroad was permitted to make a sort of headquarters in the town, and not a case of yellow fever has occurred.——Dr. C. M. Shanley, who did such yeoman volunteer service along Bayou Barataria, died of a relapse of yellow fever. In every sense of the word he died a martyr, giving his life that others might live and that he might do his duty. Well-to-do and serving without remuneration under most exhausting conditions, he was truly a hero and died a hero's death.——Dr. Szabary of New Orleans is under two charges of failing to report cases of yellow fever. ——For the week of October 2 to 9 inclusive there were reported in New Orleans only 170 new cases of yellow fever, with 17 deaths. These figures clearly demonstrate the steady and progressive diminution of the epidemic.——There has been one death from yellow fever in Chicago—a refugee, of course.

CANADA.

Sanatorium for Tuberculosis in Hamilton.—Twenty thousand dollars have been subscribed at Hamilton, Ont., for the establishment of a consumption sanitarium.

Protestant Hospital for the Insane.—In the Protestant Hospital for the Insane at Verdun, near Montreal, during the week ending October 3 there were seven admissions; four patients were discharged cured, and two discharged on trial. There were four deaths.

Provincial Jubilee Hospital, Victoria, B. C.—The number of patients admitted into the wards of the Provincial Jubilee Hospital, Victoria, B. C., during the month of August was 103 and the total treated was 143. The free patients treated were 62, the daily average being 56.29.

The New Suburban Hospital.—In Caughnawaga, a historical Indian village adjacent to Montreal, last week Archbishop Bruchesi formally opened a new hospital, which contains two public wards for men and women and several private and semiprivate rooms and in all has accommodation for 40 persons.

Vital Statistics in Toronto.—The regular monthly report of the medical health officer shows that during September there were 42 cases of typhoid fever reported, as against 2 cases in August and 19 in September, 1904. The number of births were 497; deaths, 309, and marriages, 294. During the first nine months of 1905 the city supported 181 patients in the hospitals, as compared with 151 for the same period during 1904.

Montreal General Hospital.—At the regular quarterly meeting of the board of governors of the Montreal General Hospital Dr. Craik gave an interesting account of the growth of this institution. In 1854 he said there were eight nurses, while the number of patients was between 80 and 90. During the quarter ending June 30 there had been treated 803 patients, and there were 55 deaths, 26 occurring within three days of admission. Dr. R. P. Campbell was appointed medical superintendent for another year.

Munificent Donations to Toronto General Hospital.—Over $250,000 was subscribed in Toronto during the week ending October 7, by eminent citizens for the new Toronto General Hospital. Senator Cox gave $100.000; Mr. E. R. Wood, $25,000; Mr. Timothy Eaton, $50.000; Mr. E. B. Osler, M.P. (a brother of Dr. William Osler), $25.000; Mr. J. W. Flavelle, the chairman of the Hospital Trust, $25,000; Mr. H. D. Warren, $10,000; Mr. P. C. Larkin, a member of the Hospital Trust, $10,000, and Mr. B. E. Walker, $10,000.

Winnipeg and the West.—The medical practitioners in Saskatchewan are organizing into an association and will seek affiliation with the Canadian Medical Association. Dr. G. A. Charlton, Regina, is the secretary-treasurer.——There were 229 deaths in Winnipeg during the month of September, the largest number for one month in the history of that city. Thirty-seven persons died from typhoid fever.——Three hundred and fifty-five patients were in the Winnipeg General Hospital during the week ending September 30, of whom 246 were men, 75 women and 35 children; 85 outpatients were also treated.

Ontario Vital Statistics.—During August, 1905, there were 2,200 deaths in the province of Ontario. For the same month last year there were 2,024. The increase in 1905 is thought to be due to a greater accuracy in making returns. There is a marked decrease in deaths from scarlet fever, diphtheria and typhoid, while the total reported outbreaks fell from 823 to 741. There were only 2 deaths out of 30 reported cases of scarlet fever, as against 9 out of 132 for the same month last year. There were fewer cases of tuberculosis reported, the number being 153, with 147 deaths. There were 256 cases of typhoid, as against 293 in August, 1904. The cases of whooping cough numbered 141, with 16 deaths.

Personal.—Dr. J. A. Hutchison, Montreal, chief surgeon of the Grand Trunk Railway, has been appointed chief surgeon of the Grand Trunk Pacific Railway, with headquarters at Montreal.——Dr. A. Lapthorn Smith, Montreal, has returned from a trip to Europe.——Dr. Victor C. Vaughan, dean of the medical department of the University of Michigan, delivered the opening lecture at Toronto University on October 3.——Dr. W. H. F. Addison, house surgeon of Toronto General Hospital, has been appointed lecturer on histology in the University of Pennsylvania.——On leaving Kingston for Toronto, Dr. C. K. Hospital, was presented with an address and a cabinet of silver.

Toronto Western Hospital.—In 1896 the Toronto Western Hospital began work in a small house on a residential street in that city. To-day it has a splendid set of buildings, fine grounds and accommodation for 60 patients, while in tents on the grounds there is accommodation for 55 more. An addition has recently been completed for a maternity department, and another annex has just been erected at a cost of $10,000. It is intended shortly to erect a nurses' residence to cost $25,000. A feature of this hospital has been its wide application of the open-air treatment of disease which for the past three or four years has been carried out very successfully. Bequests have recently been made to the amount of $50,000. Another feature of this hospital is that any practitioner in good standing may attend all public ward patients sent in under his care.

The Montreal Maternity Hospital.—Dr. J. Chalmers Cameron, physician at the Maternity Hospital, Montreal, entertained over 400 friends of the institution on October 6. The occasion was a goodby to the old building, a new one having been completed and made ready for occupation. The Montreal Maternity Hospital was founded in 1848 for the purpose of giving instruction in obstetrics to the students of McGill University. The total number of cases attended to in this institution during the past official year was 400, of which number 110 were out-of-town cases, the entire number being an advance of 78 over the preceding year. The training school for nurses was established in 1896 and since that time 80 nurses have been graduated therefrom. The earliest by-laws of the institution provided that the professor of obstetrics at McGill should always be the physician in attendance at this hospital.

Montreal Statistics for 1904.—Dr. Laberge, medical health officer for the city of Montreal, has completed his report for the year 1904. Heretofore Montreal has been credited with an exceedingly high death rate, owing to the fact that illegitimate and prematurely born infants were always included in the list. Including the mortality among the prematurely born and the illegitimate the death rate is 23.39 per 1,000 of the population. Excluding only the deaths among the viable prematurely born infants the rate is 22.48; excluding only the illegitimate (494), and taking in the viable prematurely born, the rate is 27.71. Excluding both the prematurely born and the illegitimate the rate was 20.08. At this rate the death rate in Montreal was lower in 1904 than in Liverpool, Dublin. Belfast, St. Petersburg, Moscow, Breslau, Prague, New York, Venice. and higher than in Birmingham, Munich, Baltimore, Glasgow and Milan. The total number of births in 1904 gave a rate of 35.96 per 1,000 of population, which was 0.23 less than in 1903. This was higher than in Toronto (24.2), and in New York (28.9). The marriage rate for 1904 was 10.21 per 1.000. or 0.5 higher than in 1903.

FOREIGN.

British Commission to Study American Insane.—It is reported that a royal commission has been appointed to visit America to study American methods of caring for the insane.

Diphtheria in Mexico.—It is reported that many cases of diphtheria have occurred in Santa Isabel, in the state of Chihuahua. The board of health of the city of Chihuahua has sent Dr. Terreros to aid in combating the disease, which is becoming epidemic in character.

Politzer's Retirement.—There is scarcely a branch of otology to which Prof. Adam Politzer of Vienna has not contributed in some way, and his works have been translated into all civilized tongues. He celebrated his seventieth birthday October 1, and this is the signal, according to Austrian regulations, for his retirement from his chair in the university, as he has reached the age limit.

Conditions of Bequest to Medical Charity.—A cable dispatch states that a money lender at Naples recently committed suicide, bequeathing his large fortune to the local home for incurables under condition that a memorial tablet be placed in each ward with an inscription to the effect that the money which he made from the rich and which the rich had wrested from the poor, now returns to the poor.

Nothnagel's Last Notes.—After the death last summer of Prof. H. Nothnagel of Vienna, a paper was found on his desk on which he had written out notes taken during the fatal attacks of angina pectoris. The last *Deutsche med. Wochft.* gives a photographic reproduction of the twenty-three lines. They are in German, but the characters are those we use—not the cramped German script. It commences: "Stenocardiac attacks with extremely violent pains. Pulse during attack very different, sometimes slow 56-60, regular with high tension, then accelerating, 80-90, even and regular, finally completely arrhythmic, irregular, now fast, now slow, with varying tension. The first consciousness of these attacks dates from three or four years back, at first very faint, but gradually becoming more and more pronounced. The true paroxysms with violent pains first appeared five or six days ago. Written July 6, 1905, late in the evening, after I have just had three severe attacks." The next paroxysm proved fatal.

Extravagant Tribute to Zoege von Manteuffel.—The commander-in-chief of the Russian forces, General Linewitsch, wrote a very complimentary letter to Prof. Zoege von Manteuffel on his leaving the seat of war to resume his duties at St. Petersburg. The general stated that God alone knew how many men the other had saved from death, and how many fathers and bread-winners had been returned to their families as the results of his efforts. Both in the hospitals at the rear of the army and in the front after the battles he had always been a model of devoted and blessed service. Heedless of shot and shell, he had been indefatigable in giving first aid to the wounded and aiding to remove them out of range of danger. Then, after the battles, instead of seeking a well-earned rest, he went to the hospitals to devote his energies again to the relief of the suffering. As a model for the younger physicians, and for all, his influence was far reaching. Linewitsch concluded by expressing his gratitude personally and in the name of the Russian soldiery. Manteuffel passed through the campaign without a scratch, but was hit by a flying missile after his return to his home city. He has now recovered from the injury.

Plague and Smallpox in India.—According to *Public Health Reports*, the report on the sanitary administration of the Punjab shows that cholera did not prevail in any severe epidemic form in the province during the year, the total mortality amounting to only 716—that is, 0.04 per mille of population. There are about 33,000 towns and villages in the province, and of these there were only 107 in which deaths from cholera were reported. In 10 whole districts not a single death was registered, in 12 others the total of deaths did not exceed 70, and in the remaining 6 districts the affected area was extremely limited. The report, however, throws no light on the causes of this distribution. Smallpox, unlike cholera, appears to have kept its ground instead of retreating. The deaths attributed to that epidemic during the year under review numbered 9,624, which shows a rate of 0.48 per mille—that is, a little over the mean ratio of the previous five years, though 0.3 lower than that of 1903. The highest mortality, as is very often the case, was registered in the month of May and the lowest in October. In a few districts, however, the epidemic declined after reaching its maximum in the month of January, notably in the case of Attock. As regards seasonable prevalence, plague and smallpox follow a similar course. Plague, like smallpox, breaks out on the approach of the cold season, increases steadily in the winter, attains its maximum intensity by about the same time as or some weeks earlier than smallpox, and declines with the commencement of the hot weather. In plague the decadence is rapid, while in the case of smallpox it is gradual, but on the whole the two epidemics exhibit a curious inclination to march hand in hand.

First International Surgical Congress.—The success of this gathering of surgeons from around the world surpassed all expectations. Nearly 500 members assembled, and all were enthusiastic over the opportunity thus afforded for discussion of a few of the most vital questions in surgery. The communications were restricted to those bearing on the six questions that had been selected by the committee of arrangements as mentioned in these columns on page 1046 of the last volume. The program there outlined was carried out in every particular. Summaries of the main addresses had been mailed to all the members of the association in time for the discussions following the addresses to be intelligent and fruitful. Brief daily reports of the proceedings were also issued every morning. The congress was not an open one, but merely the first meeting of the newly organized International Surgical Association, which now numbers 700 members. The congress was held at Brussels, September 18 to 23. Kocher of Berne presided, and American surgeons were remarkably well represented, not only in numbers but in scientific prominence. Every day brought new and stimulating discussions, the fruits of which will undoubtedly be in evidence at the next congress, to be held three years from now. The president's address was devoted to the progress realized in the campaign against cancer and appeal for general co-operation in the campaign of prevention which the Germans have so successfully commenced, especially Winter's energetic propaganda. (Winter's work was described in The Journal, xliii, p. 230.) W. W. Keen of Philadelphia, ex-president of the American Medical Association, delivered one of the four addresses on the first subject on the program, "Value of the Blood Count in Surgery." The other subjects were: "Hypertrophied Prostate," "Diagnosis of Surgical Kidney Affections," and "Surgical Intervention in Non-malignant Stomach Affections," "Tuberculosis of the Joints" and "Peritonitis." Gastric affections elicited the liveliest discussion, Kocher declaring in summarizing that gastric ulcer belongs to the surgeon, and that he could not understand why it is always the physician who decides what belongs to medicine and what to surgery. Monprofit of Angers goes so far as to claim that surgical intervention should be the rule at the first signs of slight ulceration. The *Semaine Médicale, Presse Médicale* and the *Berliner klin. Wochft.* have already published installments of the proceedings, the first with running editorial comment. Membership in the association is limited to a certain number.

LONDON LETTER.

The Standardization and Storage of Drugs.

At the annual meeting of the British Pharmaceutical Conference the president, Mr. W. Naylor, delivered an important address on this subject. He said that the present tendency to standardize preparations on the basis of one principle, regardless of other constituents which may be of therapeutic value, should be overcome. He referred to a number of potent drugs for which there is at present no satisfactory mode of standardization, including Calabar bean, hemlock, henbane, jaborandi, stramonium and strophanthus. The most recent investigations of Calabar bean point to the presence of three bases, of which eserin is supposed to represent the therapeutic properties on which the physician depends when he prescribes the official extract. The medicinal properties of hemlock may be due to one or more of the following constituents—coniin, ethyl piperidin, methyl coniin, conhydrin and pseudo-conhydrin. The experiments of Findlay show that the fluid extract of hemlock and the mixed alkaloids obtained from the drug act physiologically in a manner analogous to pure coniin. Hence the determination of the total alkaloids in a preparation of hemlock would probably serve the purpose of standardization. Speaking of storage, Mr. Naylor drew attention to the liability to loss of active principle by chemical change or precipitation on keeping. Different drugs are unequally affected. Preparations of belladonna and nux vomica appear to be the most stable, those of cinchona less so, and the liquid extract of ipecacuanha the least of all, the loss of strength in each case being due to precipitation.

"Return Cases" of Fever.

The Metropolitan Asylum's board has issued an important memorandum with reference to "return cases" of scarlet fever and diphtheria. During twelve months there have been 688 alleged infecting cases of scarlet fever, amounting to 4.1 per cent. of the total number of patients discharged. Of this number 46.5 per cent. appeared to cause "return cases." There is no laxity in the discharge of patients, but "return cases" seem to be due to premature discharge. It is thought that more extended means of isolation than at present exists might result in a considerable reduction in the number of "return cases."

Precautionary Measures Against Cerebrospinal Fever.

The local government board has issued a circular concerning cerebrospinal fever to the local sanitary authorities. It appears that cerebrospinal fever is not more prevalent in this country than it has been from time to time in the last quarter of a century, but in consequence of the prevalence of the disease in central Europe and in America the board thinks that the health authorities should be on the alert to detect it. To this end the board has issued a memorandum prepared by its medical officer, describing the characteristic symptoms of the disease and especially its minor manifestations. In the event of the discovery in any district of groups of cases of illness which might possibly be of the nature of cerebrospinal fever, a special report is to be made to the local sanitary authority by the health officer of the district and a copy of the report is to be forwarded to the local government board. The board will be prepared to render the sanitary authority any advice or assistance which may be necessary. If, in view of any special circumstances, the sanitary authority desires that cases of cerebrospinal fever should be made compulsorily notifiable in their district the board will be prepared to consider an application for extending the provisions of the infectious diseases notification act to that district for a limited period. A memorandum has been prepared by Dr. W. H. Power, health officer of the board, who states that a case of cerebrospinal fever has recently been identified in the neighborhood of London and that of several cases which have been observed in Northamptonshire four were fatal. In the course of the last forty years cerebrospinal fever has been prevalent in a considerable number of localities in England and Wales. Whether the disease is spread from person to person Dr. Power declares to be uncertain and adds that no definite knowledge as to manner of its transmission exists. Since personal infection can not be excluded, however, he recommends that the patients be isolated and measures of disinfection adopted.

The Army Medical Corps and the Boer War.

After the so-called "hospital scandals" of the Boer war a royal commission was appointed to report on the care and treatment of the sick and wounded, and to recommend measures calculated to prevent in the future such loss of life as marked that campaign, whether caused by lack of medical aid or want of sanitary organization. As a result of the report of the commission the establishment of medical officers since the war has been increased by 125, and the establishment of quartermasters, warrant officers, non-commissioned officers and men by 1,216. The question of further increase is still under consideration. As previously reported in The Journal, the pay of medical officers has been greatly improved. A college for their instruction has been opened in London and permanent buildings are in course of construction. All officers of over five years' service are required to attend a six months' course of instruction, which includes clinical teaching in the various civil hospitals in London by civilian professors. Officers passing certain standards at the examination after the course are eligible for accelerated promotion up to a period of eighteen months, and officers who distinguish themselves in selected subjects are eligible for employment as specialists with extra pay. Promotion to the higher ranks is now based on a system of strict selection based on positive merit. As the result of these regulations the supply of candidates has been of the most satisfactory nature. In March, 1902, Queen Alexandra's Imperial Military Nursing Service was established, greatly improving the conditions of service. Two hundred and fifty-nine nurses were added to the peace establishment. The scale of nurses for fixed hospitals in war has been largely augmented. Properly qualified sanitary officers have been appointed to all commands at home and abroad. It may be remembered that the ambulance wagons used in the Boer war were much too heavy and were severely condemned. To insure a satisfactory wagon a prize was offered, for which many firms competed. After exhaustive trials of many patterns a thoroughly satisfactory wagon has been selected. A special tent (a modification of the Indian E. P. tent) has been designed and has undergone successful trials. A scheme has been drawn up for the establishment of a reserve of civilian surgeons, who will receive military training. A scheme of special enlistment to provide a sufficient reserve of trained orderlies is also under consideration.

Pharmacology

Fake Pharmaceuticals.

An exchange relates the following experience of a pharmacist with a proprietary formula: A firm which makes a proprietary tablet for years had published a certain formula; recently they changed this by adding 8 grains of another drug. The pharmacist in question made inquries of several chemists about this drug and they all assured him that they had never heard of it. He then wrote to the manufacturers of the tablet, asking them if they had changed the ingredients in their preparation, and our exchange states that they made the following reply: "We have not changed the tablet—we only changed the published formula." We wonder how often the opposite is true, that the published formula remains as it was while the ingredients are changed.

Compulsory Use of Secret Proprietaries.

One of the "arguments" used by those who think it right to use secret proprietary medicines is that physicians who have not confidence in, or for any reason do not care to use, secret nostrums are not compelled to use them. Those who use this argument are correct, for we must admit that apart from the influence exerted by his misleading statements and extravagant therapeutic claims the manufacturer does not compel us to prescribe his nostrum. In championing the position of the manufacturer, however, it is not appreciated that this argument implies that the nostrum maker is conducting his business along higher ethical lines than does the physician who prescribes his product, for the physician virtually compels his patients to use these medicines of unknown therapeutic action and composition. A physician, when prescribing a secret or semi-secret proprietary remedy, ought to say to his patient: "I have directed that you buy a remedy that I know nothing about except what the manufacturer has told me." If the nostrum prescriber were thus honest with his patients how long would he have their confidence? If we consider this secret proprietary question from the patients' point of view, it would certainly appear that unless we make an honest, straightforward explanation every time we prescribe a secret or semi-secret proprietary remedy—in other words, a nostrum—we are not dealing honestly with our patients or with ourselves. Should it not appeal to us that when we compel our patients to use medicines about which, of our own knowledge, we know little or nothing, we are debasing ourselves and our profession below the rules of conduct that are followed by the admittedly commercial manufacturers of nostrums

The Great American Fraud.

SAMUEL HOPKINS ADAMS.

Gullible America will spend this year some seventy-five millions of dollars in the purchase of patent medicines. In consideration of this sum it will swallow huge quantities of alcohol, an appalling amount of opiates and narcotics, a wide assortment of varied drugs ranging from powerful and dangerous heart depressants to insidious liver stimulants; and, far in excess of all other ingredients, undiluted fraud. For fraud, exploited by the skillfullest of advertising bunco men, is the basis of the trade. Should the newspapers, the magazines and the medical journals refuse their pages to this class of advertisements, the patent medicine business in five years would be as scandalously historic as the South Sea Bubble, and the nation would be the richer not only in lives and money, but in drunkards and drug-fiends saved.

"Don't make the mistake of lumping all proprietary medicines in one indiscriminate denunciation," came warning from all sides when this series was announced. But the honest attempt to separate the sheep from the goats develops a lamentable lack of qualified candidates for the sheepfold. External remedies there may be which are at once honest in their claims and effective for their purposes; they are not to be found among the much advertised ointments or applications which fill the public prints. Cuticura may be a useful preparation, but in extravagance of advertising it rivals the most clamorous cure-all. Pond's extract, one would naturally suppose, could afford to restrict itself to decent methods, but in the recent epidemic scare in New York it traded on the public alarm by putting forth "display" advertisements headed, in heavy black type, "Meningitis," a disease in which witch hazel is about as effective as molasses. This is fairly comparable to peruna's ghoulish exploitation, for profit, of the yellow-fever scourge in New Orleans, aided by various southern papers of standing, which published as *news* an "interview" with Dr. Hartman, president of the Peruna Company. . . . Acetanilid will undoubtedly relieve headache of certain kinds; but acetanilid, as the basis of headache powders, is prone to remove the cause of the symptoms permanently by putting a complete stop to the heart action. Invariably, when taken steadily it produces constitutional disturbances of insidious development which result fatally if the drug be not discontinued, and often it enslaves the devotee to its use. Cocain and opium stop pain; but the narcotics are not the safest drugs to put into the hands of the ignorant, particularly when their presence is concealed in the "cough remedies," "soothing syrups," and "catarrhal powders" of which they are the basis. Few outside the rabid temperance advocates will deny a place in medical practice to alcohol. But alcohol, fed daily and in increasing doses to women and children, makes not for health, but for drunkenness. Far better whisky or gin unequivocally labeled than the alcohol-laden "bitters," "sarsaparillas," and "tonics" which exhilarate fatuous temperance advocates to the point of enthusiastic testimonials.

None of these "cures" really does cure any serious affection, although a majority of their users recover. But a majority, and a very large majority, of the sick recover, anyway. Were it not so—were one illness out of fifty fatal—this earth would soon be depopulated. . . .

AS TO TESTIMONIALS.

The ignorant drug-taker, returning to health from some disease which he has overcome by the natural resistant powers of his body, dips his pen in gratitude and writes his testimonial. The man who dies in spite of the patent medicine—or perhaps because of it—doesn't bear witness to what it did for him. We see recorded only the favorable results: the unfavorable lie silent. How could it be otherwise when the only avenues of publicity are controlled by the heavy advertisers? So, while many of the printed testimonials are genuine enough, *they represent not the average evidence, but the most glowing* opinions which the nostrum vender can obtain, and generally they are the expression of a low order of intelligence. . . . There it is in a nutshell; the faith cure. Not the stimulant, but the faith inspired by the advertisement and encouraged by the stimulant does the work—or seems to do it. If the public drugger can convince his patron that she is well, she *is* well—for his purposes. In the case of such diseases as naturally tend to cure themselves, no greater harm is done than the parting of a fool and his money. With rheumatism, sciatica, and that ilk, it means added pangs; with consumption, Bright's disease and other serious disorders, perhaps needless death. No onus of homicide is borne by the nostrum seller; probably the patient would have died anyway; there is no proof that the patent bottle was in any way responsible. Even if there were—and rare cases do occur where the responsibility can be brought home—there is no warning to others, because the newspapers are too considerate of their advertisers to publish such injurious items. . . .

THE MAGIC "RED CLAUSE."

With a few honorable exceptions the press of the United States is at the beck and call of the patent medicines. Not only do the newspapers modify news possibly *affecting* these interests, but they sometimes become their active agents. F. J. Cheney, proprietor of Hall's catarrh cure, devised some years ago a method of making the press do his fighting against legislation compelling makers of remedies *to publish* their formulæ, or to print on the labels the dangerous drugs contained in the medicine—a constantly *recurring bugaboo* of the nostrum-dealer. This scheme he unfolded at a meeting of the Proprietary Association of America, of which he is now president. He explained that he printed in red letters on every advertising contract a clause *providing* that the contract should become void in the event of hostile legislation, and he boasted how he had used this as a club in a case where an Illinois legislator had, as he put it, attempted to hold him up for three hundred dollars on a strike bill.

"I thought I had a plan better than this," said Mr. Cheney to his associates, "so I wrote to about forty papers and merely said: 'Please look at your contract with me and take note that if this law passes you and I must stop doing business.' The next week every one of them had an article, and Mr. Man had to go."

So *emphatically* did this device recommend itself to the increases steadily in the winter, attains its maximum intensity by about the same time as or some weeks earlier than smallpox, and declines with the commencement of the hot weather. In plague the decadence is rapid, while in the case of smallpox it is gradual, but on the whole the two epidemics exhibit a curious inclination to march hand in hand.

First International Surgical Congress.—The success of this gathering of surgeons from around the world surpassed all expectations. Nearly 500 members assembled, and all were enthusiastic over the opportunity thus afforded for discussion of a few of the most vital questions in surgery. The communications were restricted to those bearing on the six questions that had been selected by the committee of arrangements as mentioned in these columns on page 1046 of the last volume. The program there outlined was carried out in every particular. Summaries of the main addresses had been mailed to all the members of the association in time for the discussions following the addresses to be intelligent and fruitful. Brief daily reports of the proceedings were also issued every morning. The congress was not an open one, but merely the first meeting of the newly organized International Surgical Association, which now numbers 700 members. The congress was held at Brussels, September 18 to 23. Kocher of Berne presided, and American surgeons were remarkably well represented, not only in numbers but in scientific prominence. Every day brought new and stimulating discussions, the fruits of which will undoubtedly be in evidence at the next congress, to be held three years from now. The president's address was devoted to the progress realized in the campaign against cancer and appeal for general co-operation in the campaign of prevention which the Germans have so successfully commenced, especially Winter's energetic propaganda. (Winter's work was described in The Journal, xliii, p. 230.) W. W. Keen of Philadelphia, ex-president of the American Medical Association, delivered one of the four addresses on the first subject on the program, "Value of the Blood Count in Surgery." The other subjects were: "Hypertrophied Prostate," "Diagnosis of Surgical Kidney Affections," and "Surgical Intervention in Non-malignant Stomach Affections," "Tuberculosis of the Joints" and "Peritonitis." Gastric affections elicited the liveliest discussion, Kocher declaring in summarizing that gastric ulcer belongs to the surgeon, and that he could not understand why it is always the physician who decides what belongs to medicine and what to surgery. Monprofit of Angers goes so far as to claim that surgical intervention should be the rule at the first signs of slight ulceration. The *Semaine Médicale, Presse Médicale* and the *Berliner klin. Wochft.* have already published installments of the proceedings, the first with running editorial comment. Membership in the association is limited to a certain number.

LONDON LETTER.

The Standardization and Storage of Drugs.

At the annual meeting of the British Pharmaceutical Conference the president, Mr. W. Naylor, delivered an important address on this subject. He said that the present tendency to standardize preparations on the basis of one principle, regardless of other constituents which may be of therapeutic value, should be overcome. He referred to a number of potent drugs for which there is at present no satisfactory mode of standardization, including Calabar bean, hemlock, henbane, jaborandi, stramonium and strophanthus. The most recent investigations of Calabar bean point to the presence of three bases, of which eserin is supposed to represent the therapeutic properties on which the physician depends when he prescribes the official extract. The medicinal properties of hemlock may be due to one or more of the following constituents—coniin, ethyl piperidin, methyl coniin, conhydrin and pseudo-conhydrin. The experiments of Findlay show that the fluid extract of hemlock and the mixed alkaloids obtained from the drug act physiologically in a manner analogous to pure coniin. Hence the determination of the total alkaloids in a preparation of hemlock would probably serve the purpose of standardization. Speaking of storage, Mr. Naylor drew attention to the liability to loss of active principle by chemical change or precipitation on keeping. Different drugs are unequally affected. Preparations of belladonna and nux vomica appear to be the most stable, those of cinchona less so, and the liquid extract of ipecacuanha the least of all, the loss of strength in each case being due to precipitation.

"Return Cases" of Fever.

The Metropolitan Asylum's board has issued an important memorandum with reference to "return cases" of scarlet fever and diphtheria. During twelve months there have been 688 alleged infecting cases of scarlet fever, amounting to 4.1 per cent. of the total number of patients discharged. Of this number 46.5 per cent. appeared to cause "return cases." There is no laxity in the discharge of patients, but "return cases" seem to be due to premature discharge. It is thought that more extended means of isolation than at present exists might result in a considerable reduction in the number of "return cases."

Precautionary Measures Against Cerebrospinal Fever.

The local government board has issued a circular concerning cerebrospinal fever to the local sanitary authorities. It appears that cerebrospinal fever is not more prevalent in this country than it has been from time to time in the last quarter of a century, but in consequence of the prevalence of the disease in central Europe and in America the board thinks that the health authorities should be on the alert to detect it. To this end the board has issued a memorandum prepared by its medical officer, describing the characteristic symptoms of the disease and especially its minor manifestations. In the event of the discovery in any district of groups of cases of illness which might possibly be of the nature of cerebrospinal fever, a special report is to be made to the local sanitary authority by the health officer of the district and a copy of the report is to be forwarded to the local government board. The board will be prepared to render the sanitary authority any advice or assistance which may be necessary. If, in view of any special circumstances, the sanitary authority desires that cases of cerebrospinal fever should be made compulsorily notifiable in their district the board will be prepared to consider an application for extending the provisions of the infectious diseases notification act to that district for a limited period. A memorandum has been prepared by Dr. W. H. Power, health officer of the board, who states that a case of cerebrospinal fever has recently been identified in the neighborhood of London and that of several cases which have been observed in Northamptonshire four were fatal. In the course of the last forty years cerebrospinal fever has been prevalent in a considerable number of localities in England and Wales. Whether the disease is spread from person to person Dr. Power declares to be uncertain and adds that no definite knowledge as to manner of its transmission exists. Since personal infection can not be excluded, however, he recommends that the patients be isolated and measures of disinfection adopted.

The Army Medical Corps and the Boer War.

After the so-called "hospital scandals" of the Boer war a royal commission was appointed to report on the care and treatment of the sick and wounded, and to recommend measures calculated to prevent in the future such loss of life as marked that campaign, whether caused by lack of medical aid or want of sanitary organization. As a result of the report of the commission the establishment of medical officers since the war has been increased by 125, and the establishment of quartermasters, warrant officers, non-commissioned officers and men by 1,216. The question of further increase is still under consideration. As previously reported in The Journal, the pay of medical officers has been greatly improved. A college for their instruction has been opened in London and permanent buildings are in course of construction. All officers of over five years' service are required to attend a six months' course of instruction, which includes clinical teaching in the various civil hospitals in London by civilian professors. Officers passing certain standards at the examination after the course are eligible for accelerated promotion up to a period of eighteen months, and officers who distinguish themselves in selected subjects are eligible for employment as specialists with extra pay. Promotion to the higher ranks is now based on a system of strict selection based on positive merit. As the result of these regulations the supply of candidates has been of the most satisfactory nature. In March, 1902, Queen Alexandra's Imperial Military Nursing Service was established, greatly improving the conditions of service. Two hundred and fifty-nine nurses were added to the peace establishment. The scale of nurses for fixed hospitals in war has been largely augmented. Properly qualified sanitary officers have been appointed to all commands at home and abroad. It may be remembered that the ambulance wagons used in the Boer war were much too heavy and were severely condemned. To insure a satisfactory wagon a prize was offered, for which many firms competed. After exhaustive trials of many patterns a thoroughly satisfactory wagon has been selected. A special tent (a modification of the Indian E. P. tent) has been designed and has undergone successful trials. A scheme has been drawn up for the establishment of a reserve of civilian surgeons, who will receive military training. A scheme of special enlistment to provide a sufficient reserve of trained orderlies is also under consideration.

Pharmacology

Fake Pharmaceuticals.

An exchange relates the following experience of a pharmacist with a proprietary formula: A firm which makes a proprietary tablet for years had published a certain formula; recently they changed this by adding 8 grains of another drug. The pharmacist in question made inquries of several chemists about this drug and they all assured him that they had never heard of it. He then wrote to the manufacturers of the tablet, asking them if they had changed the ingredients in their preparation, and our exchange states that they made the following reply: "We have not changed the tablet—we only changed the published formula." We wonder how often the opposite is true, that the published formula remains as it was while the ingredients are changed.

Compulsory Use of Secret Proprietaries.

One of the "arguments" used by those who think it right to use secret proprietary medicines is that physicians who have not confidence in, or for any reason do not care to use, secret nostrums are not compelled to use them. Those who use this argument are correct, for we must admit that apart from the influence exerted by his misleading statements and extravagant therapeutic claims the manufacturer does not compel us to prescribe his nostrum. In championing the position of the manufacturer, however, it is not appreciated that this argument implies that the nostrum maker is conducting his business along higher ethical lines than does the physician who prescribes his product, for the physician virtually compels his patients to use these medicines of unknown therapeutic action and composition. A physician, when prescribing a secret or semi-secret proprietary remedy, ought to say to his patient: "I have directed that you buy a remedy that I know nothing about except what the manufacturer has told me." If the nostrum prescriber were thus honest with his patients how long would he have their confidence? If we consider this secret proprietary question from the patients' point of view, it would certainly appear that unless we make an honest, straightforward explanation every time we prescribe a secret or semi-secret proprietary remedy—in other words, a nostrum—we are not dealing honestly with our patients or with ourselves. Should it not appeal to us that when we compel our patients to use medicines about which, of our own knowledge, we know little or nothing, we are debasing ourselves and our profession below the rules of conduct that are followed by the admittedly commercial manufacturers of nostrums

The Great American Fraud.

SAMUEL HOPKINS ADAMS.

Gullible America will spend this year some seventy-five millions of dollars in the purchase of patent medicines. In consideration of this sum it will swallow huge quantities of alcohol, an appalling amount of opiates and narcotics, a wide assortment of varied drugs ranging from powerful and dangerous heart depressants to insidious liver stimulants; and, far in excess of all other ingredients, undiluted fraud. For fraud, exploited by the skillfullest of advertising bunco men, is the basis of the trade. Should the newspapers, the magazines and the medical journals refuse their pages to this class of advertisements, the patent medicine business in five years would be as scandalously historic as the South Sea Bubble, and the nation would be the richer not only in lives and money, but in drunkards and drug-fiends saved.

"Don't make the mistake of lumping all proprietary medicines in one indiscriminate denunciation," came warning from all sides when this series was announced. But the honest attempt to separate the sheep from the goats develops a lamentable lack of qualified candidates for the sheepfold. External remedies there may be which are at once honest in their claims and effective for their purposes; they are not to be found among the much advertised ointments or applications which fill the public prints. Cuticura may be a useful preparation, but in extravagance of advertising it rivals the most clamorous cure-all. Pond's extract, one would naturally suppose, could afford to restrict itself to decent methods, but in the recent epidemic scare in New York it traded on the public alarm by putting forth "display" advertisements headed, in heavy black type, "Meningitis," a disease in which witch hazel is about as effective as molasses. This is fairly comparable to peruna's ghoulish exploitation, for profit, of the yellow-fever scourge in New Orleans, aided by various southern papers of standing, which published as *news* an "interview" with Dr. Hartman, president of the Peruna Company. . . . Acetanilid will undoubtedly relieve headache of certain kinds; but acetanilid, as the basis of headache powders, is prone to remove the cause of the symptoms permanently by putting a complete stop to the heart action. Invariably, when taken steadily it produces constitutional disturbances of insidious development which result fatally if the drug be not discontinued, and often it enslaves the devotee to its use. Cocain and opium stop pain; but the narcotics are not the safest drugs to put into the hands of the ignorant, particularly when their presence is concealed in the "cough remedies," "soothing syrups," and "catarrhal powders" of which they are the basis. Few outside the rabid temperance advocates will deny a place in medical practice to alcohol. But alcohol, fed daily and in increasing doses to women and children, makes not for health, but for drunkenness. Far better whisky or gin unequivocally labeled than the alcohol-laden "bitters," "sarsaparillas," and "tonics" which exhilarate fatuous temperance advocates to the point of enthusiastic testimonials.

None of these "cures" really does cure any serious affection, although a majority of their users recover. But a majority, and a very large majority, of the sick recover, anyway. Were it not so—were one illness out of fifty fatal—this earth would soon be depopulated. . . .

AS TO TESTIMONIALS.

The ignorant drug-taker, returning to health from some disease which he has overcome by the natural resistant powers of his body, dips his pen in gratitude and writes his testimonial. The man who dies in spite of the patent medicine—or perhaps because of it—doesn't bear witness to what it did for him. We see recorded only the favorable results: the unfavorable lie silent. How could it be otherwise when the only avenues of publicity are controlled by the heavy advertisers? So, while many of the printed testimonials are genuine enough, they represent not the average evidence, but the most glowing opinions which the nostrum vender can obtain, and generally they are the expression of a low order of intelligence. . . . There it is in a nutshell; the faith cure. Not the stimulant, but the faith inspired by the advertisement and encouraged by the stimulant does the work—or seems to do it. If the public drugger can convince his patron that she is well, she *is* well—for his purposes. In the case of such diseases as naturally tend to cure themselves, no greater harm is done than the parting of a fool and his money. With rheumatism, sciatica, and that ilk, it means added pangs; with consumption, Bright's disease and other serious disorders, perhaps needless death. No onus of homicide is borne by the nostrum seller; probably the patient would have died anyway; there is no proof that the patent bottle was in any way responsible. Even if there were—and rare cases do occur where the responsibility can be brought home—there is no warning to others, because the newspapers are too considerate of their advertisers to publish such injurious items. . . .

THE MAGIC "RED CLAUSE."

With a few honorable exceptions the press of the United States is at the beck and call of the patent medicines. Not only do the newspapers modify news possibly affecting these interests, but they sometimes become their active agents. F. J. Cheney, proprietor of Hall's catarrh cure, devised some years ago a method of making the press do his fighting against legislation compelling makers of remedies to publish their formulæ, or to print on the labels the dangerous drugs contained in the medicine—a constantly recurring bugaboo of the nostrum-dealer. This scheme he unfolded at a meeting of the Proprietary Association of America, of which he is now president. He explained that he printed in red letters on every advertising contract a clause providing that the contract should become void in the event of hostile legislation, and he boasted how he had used this as a club in a case where an Illinois legislator had, as he put it, attempted to hold him up for three hundred dollars on a strike bill.

"I thought I had a plan better than this," said Mr. Cheney to his associates, "so I wrote to about forty papers and merely said: 'Please look at your contract with me and take note that if this law passes you and I must stop doing business.' The next week every one of them had an article, and Mr. Man had to go."

So emphatically did this device recommend itself to the assemblage that many of the large firms took up the plan, and now the "red clause" is a familiar device in the trade.[1] . . . To what length daily journalism will go at the instance of the business office was shown in the great advertising campaign of Paine's celery compound some years ago. The nostrum's agent called at the office of a prominent Chicago newspaper and spread before its advertising manager a full-page advertisement, with blank spaces in the center.

"We want some good, strong testimonials to fill out with," he said.

"You can get all of those you want, can't you?" asked the newspaper manager.

"Can *you?*" returned the other. "Show me four or five strong ones from local politicians and you get the ad."

FAKE TESTIMONIALS.

That day reporters were assigned to secure testimonials with photographs which subsequently appeared in the full-page advertisement as promised. As for the men who permitted the use of their names for this purpose, several of them afterward admitted that they had never tasted the "compound," but that they were willing to sign the testimonials for the joy of appearing in print as "prominent citizens." . . .

MEDICAL JOURNALS ALSO.

One might expect from the medical press freedom from such influences. The control is as complete, though exercised by a class of nostrums somewhat differently exploited, but essentially the same. Only "ethical" preparations are permitted in the representative medical press, that is, articles not advertised in the lay press. Yet this distinction is not strictly adhered to. "Syrup of figs," for instance, which makes widespread pretense in the dailies to be an extract of the fig, advertises in the medical journals for what it is, a preparation of senna. Antikamnia, an "ethical" proprietary compound, for a long time exploited itself to the profession by a campaign of ridiculous extravagance, and is to-day by the extent of its reckless use on the part of ignorant laymen a public menace. Recently an article announcing a startling new drug discovery and signed by a physician was offered to a standard medical journal, which declined it on learning that the drug was a proprietary preparation. The contribution returned to the editor with an offer of payment at advertising rates if it were printed as editorial reading matter, only to be rejected on the new basis. Subsequently it appeared simultaneously in more than twenty medical publications as reading matter. There are to-day very few medical publications which do not carry advertisements conceived in the same spirit and making much the same exhaustive claims as the ordinary quack "ads" of the daily press, and still fewer that are free from promises to "cure" diseases which are incurable by any medicine. Thus the medical press is as strongly enmeshed by the "ethical" druggers as the lay press is by Paine, "Dr." Kilmer, Lydia Pinkham, Dr. Hartman, "Hall" of the "red clause" and the rest of the edifying band of life-savers, leaving no agency to refute the megaphone exploitation of the frauds. What opposition there is would naturally arise in the medical profession, but this is discounted by the proprietary interests. . . .

THE DOCTORS ARE INVESTIGATING.

The physicians seem to have awakened, somewhat tardily, indeed, to counter-attack. The American Medical Association has organized a Council of Pharmacy and Chemistry to investigate and pass on the "ethical" preparations advertised to physicians, with a view to listing those which are found to be reputable and useful. That this is regarded as a direct assault on the proprietary interests is suggested by the protests, eloquent to the verge of frenzy in some cases, emanating from those organs which the manufacturers control. Already the council has issued some painfully frank reports on products of imposingly scientific nomenclature; and more are to follow. . . . Legislation is the most obvious remedy, pending the enlightenment of the general public or the awakening of the journalistic conscience. But legislation proceeds slowly and always against opposition, which may be measured in practical terms as $250,000,000 at stake on the other side. I note in the last report of the Proprietary Association's annual meeting the significant statement that "the heaviest expenses were incurred in legislative work." Most of the legislation must be done by states, and we have seen in the case of the Hall catarrh contract how readily this may be controlled. . . .

A POSTOFFICE REPORT.

That the advertising and circular statements circulated through the mails were materially and substantially false, with the result of cheating and defrauding those into whose hands the statements came;

That, while the remedies did possess medicinal properties, these were not such as to carry out the cures promised;

That the advertiser knew he was deceiving;

That in the sale and distribution of his medicines the complainant made no inquiry into the specific character of the disease in any individual case, but supplied the same remedies and prescribed the same mode of treatment to all alike.

Should the department apply these principles to the patent medicine field generally, a number of conspicuous nostrums would cease to be patrons of Uncle Sam's mail service.

Some states have made a good start in the matter of legislation, among them Michigan, which does not, however, enforce its recent strong law. Massachusetts, which has done more, through the admirable work of its State Board of Health, than any other agency to educate the public on the patent medicine question, is unable to get a law restricting this trade. In New Hampshire, too, the proprietary interests have proven too strong, and the Mallonee Bill was destroyed by the almost united opposition of a "red-clause" press. North Dakota proved more independent. After Jan. 1, 1906, all medicines sold in that state, except on physicians' prescriptions, which contain chloral, ergot, morphin, opium, cocain, bromin, iodin, or any of their compounds or derivatives, or more than 5 per cent. of alcohol, must so state on the label. When this bill became a law the Proprietary Association of America proceeded to blight the state by resolving that its members should offer no goods for sale there. . . .

Many dangerous and health-destroying compounds will escape through sheer inconspicuousness. I can touch on only a few of those which may be regarded as typical: the alcohol stimulators, as represented by peruna, Paine's celery compound, and Duffy's pure malt whisky (advertised as an exclusively medical preparation); the catarrh powders, which breed cocain slaves, and the opium-containing soothing syrups, which stunt or kill helpless infants; the consumption cures, perhaps the most devilish of all, in that they destroy hope where hope is struggling against bitter odds for existence; the headache powders, which enslave so insidiously that the victim is ignorant of his own fate; the comparatively harmless fake as typified by that marvelous product of advertising and effrontery, liquozone; and, finally, the system of exploitation and testimonials on which the whole vast system of bunco rests, as on a flimsy but cunningly constructed foundation.—Excerpts from *Collier's Weekly*, Oct. 7, 1905.

Correspondence

Spirochaeta Pallida in the Lesions of Syphilis.

San Francisco, Oct. 2, 1905.

To the Editor:—Since Schaudinn and Hoffmann described a fine corkscrew-like organism in the lesions of syphilis in May of this year various confirmatory reports have been published on the continent of Europe and in England, but as yet I have seen no reports of the demonstration of the organism in this country. It, therefore, seems proper to report the finding of the *Spirochæta pallida* in two case of untreated secondary syphilis which have lately been under observation in this hospital.

The *S. pallida* was demonstrated in a smear made from a papule located on the patient's back, that is, as far away from the mouth, anus and genitals as it was possible to get, in order to avoid the spirobacteria which normally occur in those regions. In the second case the smear was made from a mucous patch in the mouth. Both preparations showed many organisms, there being frequently two or even three in a field.

Schaudinn and Hoffmann used the Giemsa modification of the Romanowsky stain in their work; but, as that was not obtainable in this market, I used the Romanowsky stain as modified by Wright, and used it in exactly the same way as it is used for malarial blood, except that it remained on the slide for twenty-four hours at room temperature. This gave very clear and satisfactory pictures.

In one case of ulcerating epithelioma and in nine cases of syphilis which had been actively treated the organism was not to be found.

This fact, that in treated cases the organism can not be shown, is, to my mind, a strong argument for its etiologic importance. The conditions are, therefore, just the same as in another protozoan disease, namely, malaria, where the first dose of quinin causes the parasites to disappear.

---

[1] The following is the exact wording of the clause referred to: "It is mutually agreed that this contract is void, if any law is enacted by your state restricting or prohibiting the manufacture or sale of proprietary medicines."

The *S. pallida* can not very well be mistaken for anything else when we remember that it is an extremely fine corkscrew spiral, which is only seen with high magnification; I have used a four Lietz ocular and twelfth objective and the very brightest possible illumination and wide open diaphragm. It shows no structure whatever, and nothing but its form can be made out.

The Post Hospital, Presidio. F. F. Russell.

Behring's Alleged Cure for Tuberculosis.

Fort Dodge, Iowa, Oct. 8, 1905.

To the Editor:—Another tuberculosis congress has just adjourned. Like the one which was held in London in 1900, it has been noted principally for a sensation which comes from Berlin. Koch very prematurely laid down his views that bovine tuberculosis was practically free from danger to man. In all probability he was wrong, but it has taken six years, and perhaps ten, to prove him wrong, while the tuberculous cow quietly nips the grass and distributes her bacillus-laden milk to the homes throughout the world.

And now comes Behring with a view which may or may not be right, because it is wholly untried. And if Koch was right at London, then Behring is necessarily wrong now, for his very first premise is based on the assumption that human and bovine tuberculosis are identical. Behring says that his method is still untried on man. Hence, his announcement is premature and can be productive only of harm, for all things will now wait until the truthfulness or error of his theory is made known. The wide movement of associations similar to the Iowa Association for the Study and Prevention of Tuberculosis will be checked necessarily, for the reason that the people will have reason to hope that such an effort may be unnecessary. Philanthropists will hesitate, legislatures that would have taken decisive action this winter will be deterred, and everything will wait while Behring proves that he is either right or wrong, what should have been done before his sensational announcement at Paris was made.

That he withholds his secret for a year, and according to the press interviews, for the purpose of making money out of his discovery, is not altogether commendable on his part. Were it anyone but Behring, the commercial feature of the announcement would force itself on us. J. W. Kime.

Association News

NEW MEMBERS.

List of new members of the American Medical Association for the month of September, 1905:

ALABAMA.

Borden, J. P., Greensboro.
Harkness, R. B., Birmingham.

For Dandruff.—Barie directs to rub the hairy scalp every night with a 1 to 30 solution of mercuric chlorid in alcohol. Bronson prescribes an ointment of ammoniated mercury 20 grains, calomel 40 grains, and petroleum one ounce. Apply once or twice daily. This, he says, is excellent in simple dandruff, and should be combined with an occasional shampoo.—*Denver Medical Times.*

Marriages

Merritt B. Hook, M.D., to Miss Hattie De May, at Cheyenne, Wyo.

J. A. Gibbs, M.D., to Miss Grace L. Hastings, both of Suffield, Conn., October 4.

Harold Hargraves, M.D., Maywood, Ill., to Miss Leila Lines of Chicago, October 4.

William H. Pauley, M.D., to Miss Emma Wagner, both of St. Louis, September 27.

John Dunn, M.D., Delphos, Iowa, to Miss Mary Secrest of Downey, Iowa, September 26.

William O. Lubken, M.D., to Miss Mamie Speedy, both of Johnstown, Pa., September 28.

Edwin D. Perkins, M.D., to Miss Emma N. Sheed, both of Washington, D. C., September 26.

Michael W. Harrington, M.D., Indian Orchard, Mass., to Miss Catherine Pero, September 27.

Watson Lovell Wasson, M.D., to Miss Pearl Belle Randall, both of Waterbury, Vt., October 11.

Benjamin Houston Brown, M.D., to Miss Ethel Emily Corrigan, at New York City, October 4.

Harold G. Garwood, M.D., Madrid, N. M., to Miss Annie Johnson, at Evansville, Wis., recently.

Hugh Scott, M.D., Pawnee, Okla., to Miss Willie Wallace of Dustin, I. T., at Guthrie, Okla., October 1.

Eugene Clyde Underwood, Jr., M.D., Louisville, Ky., to Miss Juanita Robinson of New Orleans, July 6.

Samuel D. Flagg, M.D., St. Paul, Minn., to Miss Jennie E. Cotton of Fort Worth, Texas, September 27.

John Blakesly Henry, M.D., Scandia, Kan., to Miss Annette Sullivan of Kansas City, Mo., October 4.

Elisha I. Hook, M.D., to Miss Nellie Montgomery, both of Chicago, at Los Angeles, Cal., September 20.

Everett Humphreys Morgan, M.D., Eagle, W. Va., to Miss Elizabeth Bovie of Gallipolis, Ohio, October 11.

William R. Smith, M.D., Grand Ridge, Ill., to Miss Katherine R. Burgett of Keithsburg, Ill., October 3.

Thomas H. Mackin, M.D., Wilkes-Barre, Pa., to Miss Helen Roselle Salmon of Reading, Pa., September 27.

John DeVinne Singley, M.D., to Miss Mara Margarette Johnston, both of Pittsburg, Pa., September 26.

J. Newton Hathaway, M.D., Chicago, to Miss Natalie L. Yonkers, at Grand Rapids, Mich., September 30.

Franklyn Evans McClure, M.D., Neenah, Wis., to Miss Marjorie Agnes Barkley of Detroit, September 26.

Todd Pope Ward, M.D., Mount Vernon, Ill., to Miss Virginia Griffith Watkins of Owensboro, Ky., September 26.

Horace P. Wilson, M.D., Mediapolis, Iowa, to Mrs. Josephine McClay Gardner of Delavan, Ill., September 28.

Forrest T. Estill, M.D., Colorado Springs, Colo., to Mrs. Emma Harselle Cockrell, at Denver, Colo., September 30.

Harry F. Taylor, M.D., Mount Clemens, Mich., to Mrs. Maude Embrey Riviere of Columbus, Ohio, September 24.

Albert L. McGough, M.D., Detroit, to Miss Mary Cabray Wortley of Ypsilanti, Mich., at Dalton, Ga., September 25.

Harry H. Hewett, M.D., Sioux Falls, S. D., to Miss Jeannette B. Lesher of Philadelphia, at Chicago, September 20.

Fred F. Sovereign, M.D., Three Oaks, Mich., to Miss Ellen Horn of New Buffalo, Mich., at La Porte, Ind., September 27.

Waller Stephens Herndon, M.D., Lexington, Ky., to Miss Emily Shields Cunningham of Mount Sterling, Ky., October 11.

Paul B. Dunn, M.D., Mahanoy City, Pa., to Miss Theresa Meary, formerly of Mahanoy Plane, at Philadelphia, September 29.

Washington Berry Grove, M.D., U. S. Navy, to Miss Elizabeth Pascoe Thomson, at Summit Point, Jefferson County, W. Va., October 11.

Deaths

John Arvid Ouchterlony, M.D. University of the City of New York, 1861, of Louisville, Ky., died October 9, aged 67. He was born in Sweden, June 24, 1838, his father being an officer in the Swedish army. During the Civil War he entered the service of the United States as surgeon and served throughout the war. Prior to 1863 he was in the hospitals in and about Louisville, where he afterward made his home. In 1864 he was appointed lecturer on clinical medicine in the University of Louisville. In 1865 he resigned from the Army. He was one of the founders of the Louisville Medical College, assuming the chair of materia medica, therapeutics and clinical medicine, which position he held until the autumn of 1876. He later was professor of practice of medicine in the Kentucky School of Medicine, of therapeutics and clinical medicine in the University of Louisville, and later of medicine and clinical medicine in the same institution, which position he held up to the time of his death. He was president of the Kentucky State Medical Association in 1890. In 1892 the University of Notre Dame conferred on him the degree of doctor of laws. In 1890 he was elected a member of the Swedish Antiquarian Society, and in 1891 he received from the Swedish Royal Academy the Linnæan gold medal. He was knighted by King Oscar of Sweden, and Pope Leo XIII conferred the knighthood of the Order of St. Gregory the Great on him. Dr. Ouchterlony was a close student and has contributed much of value to medical literature. His library was one of the largest in the state, embracing books on high-class literature, medicine and the sciences. At the time of his death Dr. Ouchterlony was a member of the board of trustees of the Public Library of Louisville.

Henry Darwin Didama, M.D. Albany (N. Y.) Medical College, 1846, dean of the Syracuse University College of Medicine, died at his home in Syracuse, N. Y., October 4, aged 82. He was born at Perryville, N. Y., June 17, 1823, the son of Dr. John Didama. He received his early education at the Cazenovia Seminary and studied medicine at Geneva Medical College and at Albany Medical College. He first settled for practice in Romulus, N. Y., and in 1851 moved to Syracuse, where he has since resided. He was a member and president of the city, Onondaga county and district medical societies, was a member of the Boston Gynecological Society, of the New York State Medical Association and of the International Medical Congress, held in Philadelphia in 1876. Since 1873 he has been professor of principles and practice of medicine and dean of the faculty of the Syracuse University College of Medicine. He served for eight years as surgeon of the Fifty-first Infantry, and later as surgeon of the Sixth Division N. G. S. N. Y. He was coroner of Syracuse and Onondaga County for twelve years. Dr. Didama was for many years a member of the American Medical Association and was one of its wheelhorses. He was vice-president in 1875 and chairman of the Section on Practice of Medicine in 1884. He always stood for that which was best, whether in science or in conduct, and few men had wider influence for good.

Thomas Milton Todd, M.D. Miami Medical College, Cincinnati, 1869; a member of the American Medical Association, and of the Medical Society of the State of California, for forty years a practitioner of East Auburn, Cal.; for thirty years physician and surgeon to the Placer County Hospital; local surgeon of the Southern Pacific System; county physician of Placer County; several times president of the Placer County Medical Society, died at his home in East Auburn, September 15, from pneumonia, after an illness of six days, aged 66.

Edwin D. Steel, M.D. The College of Medicine and Surgery of the University of Minnesota, Minneapolis, 1889, a member of the American Medical Association; for many years secretary of the Minnesota Valley Medical Society; president of the Blue Earth County Medical Society; one of the most prominent and popular practitioners of southern Minnesota, died at his home in Mankato, September 21, from uremia, after a long illness, aged 43. Members of the local medical society acted as pall-bearers at his funeral.

Norman Bruce Scott, M.D. New York University, New York City, 1844, great grand nephew of Dr. Upton Scott, Annapolis, first president of the Medical and Chirurgical Faculty of Maryland, 1799-1801; a member of the Medical and Chirurgical Faculty of Maryland, and the first president of the Washington County Medical Society; a practitioner of Hagerstown, Md., for half a century, died at his home in that city, September 21, from senile debility, after an illness of three weeks, aged 86.

Joseph Maurice Sheahan, M.D. University of Paris, France, 1879, a member of the American Medical Association, Massachusetts Medical Society and the Norfolk South District Medical Society; one of the most prominent and best beloved practitioners of southeastern Massachusetts; a member of the Quincy school board from 1886 to 1896, and chairman of the local board of health in 1888, died at his home in Quincy, September 21, after an illness of a year, aged 52.

George Gregory Carroll, M.D. University of Buffalo (N. Y.) Medical Department, 1870, a member of the New York State

Medical Association, Monroe County Medical Society, Rochester Pathological Society and the Hospital Medical Society; one of the managers of the State Industrial School in 1891; twice a member of the board of education, died at his home in Rochester, September 25, from cerebral hemorrhage, after a short illness, aged 62.

Robert Ormiston, M.D. University of Pennsylvania, 1858, of Brooklyn, member of Kings County Medical Society and Brooklyn Pathological Society; consulting physician to Brooklyn Hospital, and surgeon of the Thirteenth New York Volunteer Infantry in the Civil War, died suddenly from heart disease at Stamford, N. Y., September 19, aged 71.

Charles I. Roseberry, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1860, for several years a member of the Easton (Pa.) board of health; surgeon in the Army during the Civil War, died at his home in Easton from injuries sustained by a fall several months before, aged 74.

Little C. Osmun, M.D. Medical Department of Columbian College, Washington, D. C., 1860, surgeon in the Army during the Civil War, and in charge of the Alexandria (Va.) General Hospital, died at the residence of his daughter in Washington, D. C., September 15, from senile debility, aged 73.

Edgar Worthington, M.D. University College of Medicine, Richmond, Va., 1898, a member of the American Medical Association and a prominent and successful young practitioner of Wilmington, Del., died at his home in Wilmington, from nephritis, after a long illness, September 21, aged 35.

Charles Sumner Boynton, M.D. University of Buffalo (N. Y.) Medical Department, 1857, surgeon of the Sixty-seventh Indiana Volunteer Infantry in the Civil War, died at his home in Indianapolis, September 23, from uremia, after an illness of three years, with nephritis, aged 72.

Albert E. Powell, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892, for six years health officer of Grant County, Ind., died at his home in Marion, September 21, from tuberculosis, after an illness of three years, aged 36.

Julius J. Vaughan, M.D. College of Physicians and Surgeons in the City of New York, 1860, for forty-five years a practitioner of Springville, Mich., died at his home in that place, September 17, after an illness of several weeks, from hepatic abscess, aged 72.

Jeremiah B. Spiers, M.D. Cincinnati College of Medicine and Surgery, 1877, formerly of Port Royal, Ky., but for two years a resident of Texarkana, Texas, died suddenly from cerebral hemorrhage in the office of the health officer of that city, September 12.

Edward E. Rhoads, M.D. Jefferson Medical College, Philadelphia, 1905, secretary of the Hare Medical Society of that institution, died at his home in Reading, Pa., after an illness of two weeks, aged 31.

Dennis Buell Wiggins, M.D. Cincinnati, Ohio, 1846, for more than fifty years a practitioner of Buffalo, N. Y., died at his home in West Seneca, N. Y., September 23, after an illness of ten days, aged 83.

William L. Philips, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1874, of Mount Washington, Pa., died in Uniontown, Pa., September 9, from brain disease, aged 60.

John Briscoe, M.D. The College of Physicians and Surgeons, Baltimore, 1894, of Baltimore, died at St. Agnes' Hospital in that city, September 16, from tuberculosis, after a short illness, aged 43.

Adolph J. Vidal, M.D. Medical College of the State of South Carolina, Charleston, 1869, died at his home in Gainesville, Fla., September 21, from consumption, after a lingering illness.

James O. H. Burnham, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1880, died suddenly at his home in Bar Mills, Maine, September 21, from heart disease, aged 63.

George H. Somerville, M.D. Cleveland (Ohio) Medical College, 1879, was found dead in his office in Cleveland, September 16, it is supposed from an overdose of chloroform,, aged 48.

A. C. D. Bradshaw, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1867, died at his home in Fairfield, Iowa, September 25, after a long illness, aged 59.

George Edwin Ricker, M.D. Pennsylvania, 1878, city physician of Minneapolis, Minn., in 1903, died suddenly at his office in that city, September 23, from heart disease, aged 51.

Henry Batdorf, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1876, died after an illness of eight months, at his home in Bethel, Pa., aged 56.

Samuel A. Whitehorn, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1852, died at his home in Los Angeles, Cal., September 6, aged 78.

John H. Switzer, M.D. Detroit College of Medicine, 1903, was shot and fatally wounded by his wife at Leaton, Mich., September 20, and died a few hours later, aged 42.

Edwin R. Armistead, M.D. University of Louisville (Ky.) Medical Department, 1853, an old citizen of Prescott, Ark., died at his home in that place, September 23.

Millard B. Sheldon, M.D. Northwestern University Medical School, Chicago, 1895, died at his home in Lake Geneva, Wis., September 9, from valvular heart disease.

George W. Neiberger, M.D. College of Physicians and Surgeons of Kansas City, Kan., 1897, died at his rooms in Kansas City, Mo., September 15, aged 36.

James H. Teasley, M.D. Louisville (Ky.) Medical College, 1890, died recently at his home in Eastman, Ga., and was buried at Hartwell, September 2.

Joseph M. Turney, M.D. University of Nashville (Tenn.) Medical Department, 1871, died at his home in Statesville, Tenn., September 11, aged 63.

John S. Berry, M.D. Medical College of Ohio, Cincinnati, 1881, died suddenly at his home in Spartanburg, Ind., and was buried September 23.

Benjamin Bowman, M.D. New York, 1865, died at his home in Chambersburg, Pa., September 20, after an illness of several months, aged 68.

O. A. Risley, M.D. Cleveland (Ohio) Medical College, 1854, died recently at his home in Cameron, Mo., and was buried September 10.

Eduardo Perugini, M.D. University of Naples, Italy, 1885, died suddenly at his home in New York City, September 22.

John C. Russ, M.D. Cincinnati, 1882, died at his home in Circleville, Ohio, from rheumatism, September 18, aged 53.

T. Edward Perkins, M.D. Pennsylvania, 1895, died at his home in Philadelphia, September 16, aged 38.

Gladys Colt Puckett, M.D. Missouri, 1903, died at her home in Kansas City, Mo., September 16, aged 26.

Book Notices

Human Physiology. Prepared with Special Reference to Students of Medicine. By. J. H. Raymond, A.M., M.D., Third Edition. Thoroughly Revised. 444 Illustrations, Some in Colors, and 4 Full-page Lithographic Plates. Cloth. Pp. 687. Price, $3.50 net. Philadelphia: W. B. Saunders & Co. 1905.

The author has evidently gone over every page of the book for the purpose of revision and to bring every subject treated up to date. Hence, while the original book was issued some thirteen or fourteen years ago, since which time immense strides have been made in certain departments of physiology, the volume before us represents the physiology of to-day.

Therapeutics ictice. H. C. Wood, M.D., LL.D. Twelfth vised and Adapted to the Eighth (1905) I tates Pharmacopeia. H. C. Wood and H. C. Pp. 907. Price $5.00 net. Philadelphia: J.

The twelfth edition of this work on therapeutics has been thoroughly revised and conforms to the new *Pharmacopeia* which became official September 1. Nearly a hundred new drugs have been added to those included in previous editions and many chapters have been entirely rewritten. In the preface the authors call attention to the fact that hyoscin is classed with the delirifacients, camphor with the cardiac stimulants, and carbolic acid with the disinfectants. While considerable attention is given to anesthesia, general, local and spinal, the only reference to the scopolamin—morphin method—which is receiving so much attention at present, is in a footnote.

Physical Diagnosis. R. C. Cabot, M.D. Third Edition, revised and enlarged: 245 Illustrations. Cloth. Pp. 577. Price, $3.00. New York: Wm. Wood & Co.

The striking feature of Cabot's work is its individuality. The personality of the author is felt on every page. One is impressed with the fact that what is stated are the views of the author gained by personal experience, and not those of some one else. That this is his aim he makes clear by his statement in the preface: "All that I have described I know by prolonged use." The book "makes no attempt to describe technic processes with which the writer has no personal familiarity, and gives no space to the description of tests which he believes to be useless."

Marriages

Dr. Didama was for many years a member of the American Medical Association and was one of its wheel-horses. He was vice-president in 1875 and chairman of the Section on Practice of Medicine in 1884. He always stood for that which was best, whether in science or in conduct, and few men had wider influence for good.

Thomas Milton Todd, M.D. Miami Medical College, Cincinnati, 1869; a member of the American Medical Association, and of the Medical Society of the State of California, for forty years a practitioner of East Auburn, Cal.; for thirty years physician and surgeon to the Placer County Hospital; local surgeon of the Southern Pacific System; county physician of Placer County; several times president of the Placer County Medical Society, died at his home in East Auburn, September 15, from pneumonia, after an illness of six days, aged 66.

Edwin D. Steel, M.D. The College of Medicine and Surgery of the University of Minnesota, Minneapolis, 1889, a member of the American Medical Association; for many years secretary of the Minnesota Valley Medical Society; president of the Blue Earth County Medical Society; one of the most prominent and popular practitioners of southern Minnesota, died at his home in Mankato, September 21, from uremia, after a long illness, aged 43. Members of the local medical society acted as pall-bearers at his funeral.

Norman Bruce Scott, M.D. New York University, New York City, 1844, great grand nephew of Dr. Upton Scott, Annapolis, first president of the Medical and Chirurgical Faculty of Maryland, 1799-1801; a member of the Medical and Chirurgical Faculty of Maryland, and the first president of the Washington County Medical Society; a practitioner of Hagerstown, Md., for half a century, died at his home in that city, September 21, from senile debility, after an illness of three weeks, aged 86.

Joseph Maurice Sheahan, M.D. University of Paris, France, 1879, a member of the American Medical Association, Massachusetts Medical Society and the Norfolk South District Medical Society; one of the most prominent and best beloved practitioners of southeastern Massachusetts; a member of the Quincy school board from 1886 to 1896, and chairman of the local board of health in 1888, died at his home in Quincy, September 21, after an illness of a year, aged 52.

George Gregory Carroll, M.D. University of Buffalo (N. Y.) Medical Department, 1870, a member of the New York State

Medical Association, Monroe County Medical Society, Rochester Pathological Society and the Hospital Medical Society; one of the managers of the State Industrial School in 1891; twice a member of the board of education, died at his home in Rochester, September 25, from cerebral hemorrhage, after a short illness, aged 62.

Robert Ormiston, M.D. University of Pennsylvania, 1858, of Brooklyn, member of Kings County Medical Society and Brooklyn Pathological Society; consulting physician to Brooklyn Hospital, and surgeon of the Thirteenth New York Volunteer Infantry in the Civil War, died suddenly from heart disease at Stamford, N. Y., September 19, aged 71.

Charles I. Roseberry, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1860, for several years a member of the Easton (Pa.) board of health; surgeon in the Army during the Civil War, died at his home in Easton from injuries sustained by a fall several months before, aged 74.

Little C. Osmun, M.D. Medical Department of Columbian College, Washington, D. C., 1860, surgeon in the Army during the Civil War, and in charge of the Alexandria (Va.) General Hospital, died at the residence of his daughter in Washington, D. C., September 15, from senile debility, aged 73.

Edgar Worthington, M.D. University College of Medicine, Richmond, Va., 1898, a member of the American Medical Association and a prominent and successful young practitioner of Wilmington, Del., died at his home in Wilmington, from nephritis, after a long illness, September 21, aged 35.

Charles Sumner Boynton, M.D. University of Buffalo (N. Y.) Medical Department, 1857, surgeon of the Sixty-seventh Indiana Volunteer Infantry in the Civil War, died at his home in Indianapolis, September 23, from uremia, after an illness of three years, with nephritis, aged 72.

Albert E. Powell, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892, for six years health officer of Grant County, Ind., died at his home in Marion, September 21, from tuberculosis, after an illness of three years, aged 36.

Julius J. Vaughan, M.D. College of Physicians and Surgeons in the City of New York, 1860, for forty-five years a practitioner of Springville, Mich., died at his home in that place, September 17, after an illness of several weeks, from hepatic abscess, aged 72.

Jeremiah B. Spiers, M.D. Cincinnati College of Medicine and Surgery, 1877, formerly of Port Royal, Ky., but for two years a resident of Texarkana, Texas, died suddenly from cerebral hemorrhage in the office of the health officer of that city, September 12.

Edward E. Rhoads, M.D. Jefferson Medical College, Philadelphia, 1905, secretary of the Hare Medical Society of that institution, died at his home in Reading, Pa., after an illness of two weeks, aged 31.

Dennis Buell Wiggins, M.D. Cincinnati, Ohio, 1846, for more than fifty years a practitioner of Buffalo, N. Y., died at his home in West Seneca, N. Y., September 23, after an illness of ten days, aged 83.

William L. Philips, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1874, of Mount Washington, Pa., died in Uniontown, Pa., September 9, from brain disease, aged 60.

John Briscoe, M.D. The College of Physicians and Surgeons, Baltimore, 1894, of Baltimore, died at St. Agnes' Hospital in that city, September 16, from tuberculosis, after a short illness, aged 43.

Adolph J. Vidal, M.D. Medical College of the State of South Carolina, Charleston, 1869, died at his home in Gainesville, Fla., September 21, from consumption, after a lingering illness.

James O. H. Burnham, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1880, died suddenly at his home in Bar Mills, Maine, September 21, from heart disease, aged 63.

George H. Somerville, M.D. Cleveland (Ohio) Medical College, 1879, was found dead in his office in Cleveland, September 16, it is supposed from an overdose of chloroform,, aged 48.

A. C. D. Bradshaw, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1867, died at his home in Fairfield, Iowa, September 25, after a long illness, aged 59.

George Edwin Ricker, M.D. Pennsylvania, 1878, city physician of Minneapolis, Minn., in 1903, died suddenly at his office in that city, September 23, from heart disease, aged 51.

Henry Batdorf, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1876, died after an illness of eight months, at his home in Bethel, Pa., aged 56.

Samuel A. Whitehorn, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1852, died at his home in Los Angeles, Cal., September 6, aged 78.

John H. Switzer, M.D. Detroit College of Medicine, 1903, was shot and fatally wounded by his wife at Leaton, Mich., September 20, and died a few hours later, aged 42.

Edwin R. Armistead, M.D. University of Louisville (Ky.) Medical Department, 1853, an old citizen of Prescott, Ark., died at his home in that place, September 23.

Millard B. Sheldon, M.D. Northwestern University Medical School, Chicago, 1895, died at his home in Lake Geneva, Wis., September 9, from valvular heart disease.

George W. Neiberger, M.D. College of Physicians and Surgeons of Kansas City, Kan., 1897, died at his rooms in Kansas City, Mo., September 15, aged 36.

James H. Teasley, M.D. Louisville (Ky.) Medical College, 1890, died recently at his home in Eastman, Ga., and was buried at Hartwell, September 2.

Joseph M. Turney, M.D. University of Nashville (Tenn.) Medical Department, 1871, died at his home in Statesville, Tenn., September 11, aged 63.

John S. Berry, M.D. Medical College of Ohio, Cincinnati, 1881, died suddenly at his home in Spartanburg, Ind., and was buried September 23.

Benjamin Bowman, M.D. New York, 1865, died at his home in Chambersburg, Pa., September 20, after an illness of several months, aged 68.

O. A. Risley, M.D. Cleveland (Ohio) Medical College, 1854, died recently at his home in Cameron, Mo., and was buried September 10.

Eduardo Perugini, M.D. University of Naples, Italy, 1885, died suddenly at his home in New York City, September 22.

John C. Russ, M.D. Cincinnati, 1882, died at his home in Circleville, Ohio, from rheumatism, September 18, aged 53.

T. Edward Perkins, M.D. Pennsylvania, 1895, died at his home in Philadelphia, September 16, aged 38.

Gladys Colt Puckett, M.D. Missouri, 1903, died at her home in Kansas City, Mo., September 16, aged 26.

Book Notices

[illegible] ired with Special Reference to Stu- [illegible] Raymond, A.M., M.D., Third Edition. [illegible] lustrations, Some in Colors, and 4 [illegible]. Cloth. Pp. 687. Price, $3.50 net. [illegible] & Co. 1905.

The author has evidently gone over every page of the book for the purpose of revision and to bring every subject treated up to date. Hence, while the original book was issued some thirteen or fourteen years ago, since which time immense strides have been made in certain departments of physiology, the volume before us represents the physiology of to-day.

THERAPEUTICS, Its Principles and Practice. H. C. Wood, M.D., LL.D. Twelfth edit [illegible] vised and Adapted to the Eighth (1905) Edit [illegible] tates Pharmacopeia. H. C. Wood and H. C. Woo [illegible] Pp. 907. Price $5.00 net. Philadelphia: J. B. [illegible]

The twelfth edition of this work on therapeutics has been thoroughly revised and conforms to the new Pharmacopeia which became official September 1. Nearly a hundred new drugs have been added to those included in previous editions and many chapters have been entirely rewritten. In the preface the authors call attention to the fact that hyoscin is classed with the delirifacients, camphor with the cardiac stimulants, and carbolic acid with the disinfectants. While considerable attention is given to anesthesia, general, local and spinal, the only reference to the scopolamin—morphin method—which is receiving so much attention at present, is in a footnote.

PHYSICAL DIAGNOSIS. R. C. Cabot, M.D. Third Edition, revised and enlarged: 245 illustrations. Cloth. Pp. 577. Price, $3.00. New York: Wm. Wood & Co.

The striking feature of Cabot's work is its individuality. The personality of the author is felt on every page. One is impressed with the fact that what is stated are the views of the author gained by personal experience, and not those of some one else. That this is his aim he makes clear by his statement in the preface: "All that I have described I know by prolonged use." The book "makes no attempt to describe technic processes with which the writer has no personal familiarity, and gives no space to the description of tests which he believes to be useless."

Herein lies, we believe, its strength and weakness. It is weak in that it is too incomplete to be put into the hands of the undergraduate to be used as a book of reference. In other words, the work is too incomplete as a guide, since all consideration of laryngoscopy, cystoscopy, ophthalmoscopy, several chemical tests of the gastric contents and of the urine, etc., are omitted. There is no misrepresentation, however, no sailing under false colors; the preface distinctly states these limitations.

The strength of the book is in its honesty and courage of the writer and his shrewdness as a clinical observer and student. While not fanatically iconoclastic, he is healthfully skeptical. Weight of authority does not prove to him the truth of a statement. He must prove it by his own experience; and *if this is at variance with the authority, well and good*; the result goes down in print just the same. Now, it is this critical spirit, this frank discussion of facts, this honest admission of his personal limitations, that livens the pages and makes one feel that one is having a heart-to-heart talk with the author; and we nod mental approval many a time as some fact is stated in a clear way, and we realize that we have inwardly believed the same, though we had never dared to say it aloud before. For the practitioner, then, the book is highly entertaining and instructive, as well as for the student, if rightly used. It is full of valuable hints.

While from the artistic point of view some of the illustrations might be improved, and while one or two are hardly intelligible, the great majority have a distinct value. The chapters on the physical diagnosis of diseases of the heart, lungs, pleura and blood are especially strong.

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

DETERIORATION OF APOMORPHIN HYDROCHLORATE.

Chicago, Oct. 6, 1905.

To the Editor:—In the *Alkaloidal Clinic*, July, 1905, Dr. M. G. Price, Mosheim, Tenn., reports a case in which he gave a sample of apomorphin *eleven years old* to a child of four who was choking to death with croup. About 1/25 of a grain was injected into the thigh and caused prompt vomiting "without depression or any untoward symptoms." Dr. Price says: "The apomorphin was very much changed in color, being of a very dark green; it had been in my hypodermic case for more than eleven years, having been purchased and placed there in 1893. Its age had no deteriorating effect on it either by way of strength or poisonous effect." I also have a letter from Dr. T. H. Williams, Germantown, Tenn., who was called on to treat a case of strychnin poisoning, the patient having taken 30 grains of this drug in mistake for quinin, and presenting the symptoms characteristic of strychnin poisoning. His life was saved by the injection, hypodermically, of 1/10 grain of apomorphin, taken from a bottle of this drug which he had had in his case for five years. The drug caused prompt emesis. The doctor says: "The apomorphin had long since run the color scale and had gotten out of the greens." The claim that apomorphin, in turning greenish to green, loses material efficiency or becomes to any practical extent poisonous, is an absurd fallacy. W. C. Abbott, M.D.

Answer.—When so delicately organized a substance as apomorphin, already a decomposition product, changes color it is safe to assume that it has undergone some marked change, chemical as well as physical. That it is well to be on the safe side in the administration of all medicines is even stronger than assumption, since it is in fact the only safe rule. The apparent fact that there is evidence that apomorphin was prompt and effective as an emetic does not in the least prove that it is either safe or wise to use any drug when in the least decomposed.

MENDEL'S INTRAVENOUS THIOSINAMIN INJECTIONS.

Scranton, Pa., Oct. 6, 1905.

To the Editor:—Please let me know the formula for the intravenous injection of thiosinamin as practiced by Dr. Mendel.

R. B. McKeage.

Answer.—Mendel does not give his formula, but uses a Merck preparation of thiosinamin, which contains 0.13 gm. of sodium salicylate with 0.2 gm. of thiosinamin "fibrolysin," in each bulb. As a rule, he makes an intramuscular injection in the buttocks. and states that not a trace of infiltration was visible on patients who had received thirty or more of these injections in the same spot. His communications have been published in the *Therapie der Gegenwart*, No. 8, and in the *Münch. med. Wochft.*, No. 4. He is known as the "apostle of intravenous medication," and his assertions have been criticised by other writers, so that his last articles have been mostly polemic. He declares that others have applied the thiosinamin in cases not at all adapted for this drug, hence their failures to obtain results as good as his.

State Boards of Registration

COMING EXAMINATIONS.

Board of Medical Examiners of State of Texas, San Antonio, October 17. Secretary, T. T. Jackson, San Antonio.

State Board of Medical Examiners of New Jersey, Trenton, October 17-18. Secretary, E. L. B. Godfrey, Camden.

State Board of Health of Illinois, The Great Northern Hotel, Chicago, October 18. Secretary, J. A. Egan, Springfield.

Louisiana State Board, New Orleans, October 20-21. Secretary, F. A. Larue, New Orleans.

State Board of Heath of Kentucky, Louisville, October 24. Secretary, J. N. McCormack, Bowling Green.

Wyoming September Report.—Dr. S. B. Miller, secretary of the Wyoming Board of Medical Examiners, reports the written examination, held Sept. 6-8, 1905. The number of subjects examined in was 11; total number of questions asked, 110; percentage required to pass, 75. The total number of candidates examined was 4, of whom 3 passed and 1 failed. Representatives of the following colleges passed:

College.	Year. Grad.	Per Cent.
PASSED.		
University of Minnesota	(1904)	82.3
University of Oregon	(1905)	81.4
Ohio Medical University	(1905)	81.8

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending October 7:

Glennan, James D., surgeon, leave of absence extended ten days.

Marrow, Charles E., asst.-surgeon, ordered from Fort Sheridan, Ill., to Chicago, Ill., for temporary duty as attending surgeon and examiner of recruits.

Truby, Albert E., asst.-surgeon, granted leave of absence for one month.

Gapen, Nelson, asst.-surgeon, granted leave of absence for one month, with permission to visit the United States.

Juenemann, George F., asst.-surgeon, granted leave of absence for fifteen days.

Cowper, Harold W., asst.-surgeon, granted leave of absence for one month on surgeon's certificate of disability to take effect on his discharge from treatment at the Army General Hospital, Presidio of San Francisco, Cal.

Williamson, Llewellyn P., asst.-surgeon, resignation of commission accepted to take effect December 15.

Lyster, Theodore C., Wadhams, Sanford H., Robbins, Chandler P., Rhoads, Thomas L., Gilchrist, Harry L., Lyster, William J. L., Persons, Elbert E., Bispham, William N., asst.-surgeons, advanced to rank of captain October 3..

Newlove, George, contract surgeon, left Fort Oglethorpe, Ga., on leave of absence for two months.

Davis, Oscar F., contract surgeon, left Fort DeSoto, Fla., for duty at Jefferson Barracks, Mo.

Ashburn, James K., contract surgeon, returned to Fort Lincoln, N. D., from duty with troops in the field.

Adair, George F., contract surgeon, left Fort Wadsworth, N. Y., and arrived at Sea Girt, N. J., for temporary duty.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending October 7:

Moore, J. M., P. A. surgeon, orders of September 27 modified; ordered to the Navy recruiting rendezvous, New York, N. Y.

Blackburn, T. C., acting asst.-surgeon, detached from duty with naval recruiting party No. 2, and ordered to the naval recruiting rendezvous, St. Louis.

Bradley, G. P., medical director, detached from the Naval Hospital, Washington, D. C., October 15, and ordered to the Navy Yard, Portsmouth, N. H., and to additional duty in command of the Naval Hospital at that place.

Dickinson, D., medical director, detached from the Navy Yard, Portsmouth, N. H., and ordered to command the Naval Hospital, Washington, D. C.

Law, H. L., surgeon, retired, detached from the naval recruiting rendezvous, Boston, and ordered home.

McCullough, F. E., surgeon, detached from the *Pensacola* and ordered to the *Albatross*.

Huntington, E. O., surgeon, detached from the *Albatross* and ordered to Washington, D. C., and report at the Navy Department.

Stuart, A., P. A. surgeon, [illegible] from the Naval Hospital, Chelsea, Mass., and ordered t [illegible] additional *duty at the* Naval Training

Michels, R. H., asst.-surgeon, ordered to the *Naval recruiting* rendezvous, Kansas City, Mo.

Elmore, B., asst.-surgeon, detached from the Naval Hospital, Washington D. C., December 1, and resignation accepted, to take effect same day.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending October 4:

Gassaway, J. M., surgeon, to rejoin station at St. Louis.

Greene, J. B., P. A. surgeon, to proceed to Port Gibson, Miss., and report to Surgeon Guiteras for special temporary duty.

McMullen, John, P. A. surgeon, to proceed to Gulfport, Miss., for instructions relative to special temporary duty at or near Scranton, Miss.

Amesse, J. W., P. A. surgeon, relieved from temporary duty at Cairo, Ill., and directed to proceed to New Orleans, and report to Surgeon J. H. White for special temporary duty.

Berry, T. D., P. A. surgeon, to proceed to Gulfport, Miss., for instructions relative to special temporary duty at or near Scranton, Miss.

McLaughlin, A. J., P. A. surgeon, relieved from duty at Hamburg, Germany. Proceed to Berlin, Germany, for duty.

Collins, G. L., asst.-surgeon, granted leave of absence for one day under paragraph 191 of the regulations.

Stewart, W. J. S., acting asst.-surgeon, leave of absence granted for thirty days from October 1, revoked.

Scott, E. B., pharmacist, granted leave of absence for seven days under paragraph 210 of the regulations.

Hall, L. P., pharmacist, granted leave of absence for two days from September 9, under paragraph 210 of the regulations.

BOARD CONVENED.

Board to meet at Tampa Bay Quarantine Statión, October 3, for physical examination of Chief Engineer H. L. Boyd, R. C. S. Detail for the board: Asst.-Surgeon R. E. Ebersole, chairman. Acting Asst.-Surgeon G. H. Altree, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the period from September 30 to October 9:

SMALLPOX—UNITED STATES.

California: Los Angeles, Sept. 16-23, 1 case; San Francisco, 1 case.

Illinois: Chicago, Sept. 23-30, 1 death; Galesburg, Sept. 23-30, 3 cases.

Ohio: Cincinnati, Sept. 22-29, 1 case.

Pennsylvania: Altoona, Sept. 23-30, 1 case.

Washington, Tacoma, Sept. 16-23, 1 case.

SMALLPOX—FOREIGN.

Africa: Cape Town, Aug. 19-26, 1 case.

Brazil: Pernambuco, Aug. 1-15, 215 deaths.

China: Hongkong, Aug. 19-26, 1 case, 1 death; Neuchwang, Aug. 5-12, 3 cases.

Ecuador: Guayaquil, Sept. 5-12, 4 cases.

France: Marseilles, Aug. 1-31, 1 death; Paris, Sept. 8-16, 22 cases, 5 deaths.

Gibraltar: Sept. 3-10, 2 cases.

India: Madras, Aug. 19-25, 8 cases.

Mexico: Dona Cecilia, Sept. 25, 1 case.

Russia: Odessa, Sept. 9-16, 4 cases, 1 death.

Spain: Barcelona, Sept. 1-10, 1 death; Cadiz, Aug. 1-31, 1 death.

YELLOW FEVER—UNITED STATES.

Florida: Brent, Sept. 26, 1 case, 1 death; Pensacola, Aug. 29-Oct. 1, 158 cases, 26 deaths.

Louisiana: Ascension Parish, to Sept. 28, 77 cases, 4 deaths; Assumption Parish, to Oct. 2, 38 cases; Avoyelles Parish, to Sept. 29, 11 cases, 2 deaths; East Baton Rouge Parish, to Sept. 30, 7 cases, 1 death; East Carroll Parish, to Oct. 2, 278 cases, 33 deaths; Iberville Parish, to Oct. 3, 30 cases, 8 deaths; Jefferson Parish, to Oct. 2, 428 cases, 46 deaths; Lafourche Parish, 381 cases, 47 deaths; Madison Parish, 307 cases, 18 deaths; Natchitoches Parish, to Sept. 27, 80 cases, 5 deaths; Orleans Parish, New Orleans, July 21-Oct. 4, 3,083 cases, 398 deaths; Plaquemines Parish, to Oct. 2, 54 cases, 8 deaths; Rapides Parish, to Oct. 3, 24 cases; St. Bernard Parish, 24 cases, 3 deaths; St. Charles Parish, to Sept. 29, 117 cases, 16 deaths; St. John the Baptist Parish, to Sept. 27, 151 cases, 14 deaths; St. Mary Parish, to Oct. 3, 756 cases, 29 deaths; St. Tammany Parish, to Oct. 2, 7 cases, 1 death; Tensas Parish, to Sept. 30, 6 cases; Terrebonne Parish, to Oct. 1, 271 cases, 13 deaths.

Mississippi: Gulfport, Aug. 15-Oct. 1, 90 cases, 2 deaths; Gulf Quarantine, July 22-Sept. 16, 65 cases, 1 death; Hamburg, Sept. 15-Oct. 1, 39 cases, 5 deaths; Mississippi City, Aug. 22-Oct. 1, 65 cases; Moss Point, to Oct. 1, 3 cases; Natchez, 62 cases, 3 deaths; Port Gibson, Sept. 27,-Oct. 1, 4 cases; Rosetta, Oct. 1, 2 cases; Scranton, Sept. 29-Oct.1, 17 cases; Vicksburg, Aug. 30-Oct. 1, 81 cases, 7 deaths.

YELLOW FEVER—FOREIGN.

Guatemala: Zacapa, Sept. 21, 18 to 20 deaths.

Honduras: Chamelicon, Sept. 8, 6 cases; Choloma, 1 case; San Pedro, Sept. 8, 2 cases, 2 deaths.

Mexico: Coatzacoalcas, Aug. 19-26, 2 cases; Vera Cruz, Sept. 9-23, 4 cases, 2 deaths.

CHOLERA—INSULAR.

Philippine Islands: Manila, Aug. 23-25, 21 cases, 17 deaths.

CHOLERA—FOREIGN.

China: Shanghai, Aug. 19-26, present.

India: Bombay, Aug. 31-Sept. 5, 1 death.

Japan: Yokohama, Aug. 13-20; 1 case, 1 death.

PLAGUE—INSULAR.

Philippine Islands: Manila, Aug. 12-19, 1 death.

PLAGUE—FOREIGN.

India: Bombay, Aug. 31-Sept. 5, 43 deaths; Karachi, Aug. 27-Sept. 3, 22 cases, 17 deaths.

Japan: Formosa, Aug. 1-31, 2 cases; 2 deaths.

Society Proceedings

COMING MEETINGS.

New York State Medical Association, New York City, October 16-19.

Medical Society of Virginia, Nofolk, October 24-27.

Hawaiian Territorial Medical Society, Honolulu, November 4.

American Academy of Medicine, Chicago, November 9-10.

Kentucky State Medical Association, Louisville, Oct. 18-20.

AMERICAN ASSOCIATION OF RAILWAY SURGEONS.

Second Annual Meeting, held in Chicago, Oct. 4-6, 1905.

The President, Dr. John E. Owens, Chicago, in the Chair.

The association has three kinds of membership—permanent members, delegates and associate members. The association is cosmopolitan and has members from Canada and Mexico.

Forty papers were read, most of them being freely discussed. One session was taken up in discussing the care of fractures; conservative treatment of compound fractures; wiring as a means of securing the best results in compound fractures of the long bones; direct fixation in fractures; fractures of the vertebral column involving the cord and its treatment; fractures of the spine; Colles' fractures; fractures of the patella and fractures of the leg. An interesting feature of the meeting was a lantern-slide exhibit of anopheles and stegomyia mosquitoes, with remarks on how freight and passengers are handled from the quarantined city, New Orleans, Dr. L. Sexton, New Orleans. The papers presented were of a higher order and more scientific than usual; the various subjects were treated by men with extensive and varied experience.

Officers Elected.

The following officers were elected for the ensuing year: President, Dr. Richard W. Corwin, Pueblo, Colo.; vice-presidents, Dr. J. H. W. Meyer, La Porte, Ind.; Dr. S. L. McCurdy, Pittsburg, Pa.; Dr. Bacon Saunders, Fort Worth, Texas; secretary, Dr. H. B. Jennings, Council Bluffs, Iowa; treasurer, Dr. T. B. Lacey, Council Bluffs, Iowa; editor, Dr. Louis J. Mitchell, Chicago; members of the executive board, Dr. W. S. Hoy, Wellston, Ohio, and Dr. J. R. Hollowbush, Rock Island, Ill.

The time and place of the next meeting are to be decided by the executive board.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Annual Meeting, held in Scranton, Sept. 26-28, 1905.

(Continued from page 1110.)

President, Dr. Adolph Koenig, Pittsburg, in the Chair.

Welcome Addresses.

An address of welcome was delivered by the Hon. Alex. T. Connell, mayor of Scranton, in which he stated that, in his opinion, if the laity would observe the established rules of preventive sanitation and hygiene, epidemics and pestilences would be markedly decreased, and that, while the science of medicine was advancing every year, there was more need for the application of the knowledge already laid down.

Dr. Daniel A. Capwell delivered the address of welcome on behalf of the Lackawanna County Medical Society. He urged on the general practitioner, practicing in a limited field in the country districts, that his work was an important one, and that the Pasteurs and the Listers must have their underworkers. He gave in some detail the evolution of medicine and the work in that direction by Harvey, Jenner, Pasteur, Lister, Roux and others, and urged the necessity of medical organization as a factor for social, professional and financial advancement.

The following delegates from other states were introduced and each made a few remarks: Dr. W. Blair Stewart, Atlantic City, N. J., delegate from the New Jersey State Medical Society; Dr. Richard H. Gibbons, New York, delegate from the New York State Medical Society, and Drs. Everett J. McKnight and Herman G. Howe, Hartford, Conn., delegates from the Connecticut State Medical Society.

Herein lies, we believe, its strength and weakness. It is weak in that it is too incomplete to be put into the hands of the undergraduate to be used as a book of reference. In other words, the work is too incomplete as a guide, since all consideration of laryngoscopy, cystoscopy, ophthalmoscopy, several chemical tests of the gastric contents and of the urine, etc., are omitted. There is no misrepresentation, however, no sailing under false colors; the preface distinctly states these limitations.

The strength of the book is in its honesty and courage of the writer and his shrewdness as a clinical observer and student. While not fanatically iconoclastic, he is healthfully skeptical. Weight of authority does not prove to him the truth of a statement. He must prove it by his own experience; and if this is at variance with the authority, well and good; the result goes down in print just the same. Now, it is this critical spirit, this frank discussion of facts, this honest admission of his personal limitations, that livens the pages and makes one feel that one is having a heart-to-heart talk with the author; and we nod mental approval many a time as some fact is stated in a clear way, and we realize that we have inwardly believed the same, though we had never dared to say it aloud before. For the practitioner, then, the book is highly entertaining and instructive, as well as for the student, if rightly used. It is full of valuable hints.

While from the artistic point of view some of the illustrations might be improved, and while one or two are hardly intelligible, the great majority have a distinct value. The chapters on the physical diagnosis of diseases of the heart, lungs, pleura and blood are especially strong.

Queries and Minor Notes

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

DETERIORATION OF APOMORPHIN HYDROCHLORATE.

Chicago, Oct. 6, 1905.

To the Editor:—In the *Alkaloidal Clinic,* July, 1905, Dr. M. G. Price, Mosheim, Tenn., reports a case in which he gave a sample of apomorphin *eleven years old* to a child of four who was choking to death with croup. About 1/25 of a grain was injected into the thigh and caused prompt vomiting "without depression or any untoward symptoms." Dr. Price says: "The apomorphin was very much changed in color, being of a very dark green; it had been in my hypodermic case for more than eleven years, having been purchased and placed there in 1893. Its age had no deteriorating effect on it either by way of strength or poisonous effect." I also have a letter from Dr. T. H. Williams, Germantown, Tenn., who was called on to treat a case of strychnin poisoning, the patient having taken 30 grains of this drug in mistake for quinin, and presenting the symptoms characteristic of strychnin poisoning. His life was saved by the injection, hypodermically, of 1/10 grain of apomorphin, taken from a bottle of this drug which he had had in his case for five years. The drug caused prompt emesis. The doctor says: "The apomorphin had long since run the color scale and had gotten out of the greens." The claim that apomorphin, in turning greenish to green, loses material efficiency or becomes to any practical extent poisonous, is an absurd fallacy.

W. C. Abbott, M.D.

Answer.—When so delicately organized a substance as apomorphin, already a decomposition product, changes color it is safe to assume that it has undergone some marked change, chemical as well as physical. That it is well to be on the safe side in the administration of all medicines is even stronger than assumption, since it is in fact the only safe rule. The apparent fact that there is evidence that apomorphin was prompt and effective as an emetic does not in the least prove that it is either safe or wise to use any drug when in the least decomposed.

MENDEL'S INTRAVENOUS THIOSINAMIN INJECTIONS.

Scranton, Pa., Oct. 6, 1905.

To the Editor:—Please let me know the formula for the intravenous injection of thiosinamin as practiced by Dr. Mendel.

R. B. McKeage.

Answer.—Mendel does not give his formula, but uses a Merck preparation of thiosinamin, which contains 0.13 gm. of sodium salicylate with 0.2 gm. of thiosinamin "fibrolysin," in each bulb. As a rule, he makes an intramuscular injection in the buttocks, and states that not a trace of infiltration was visible on patients who had received thirty or more of these injections in the same spot. His communications have been published in the *Therapie der Gegenwart,* No. 8, and in the *Münch. med. Wochft.,* No. 4. He is known as the "apostle of intravenous medication," and his assertions have been criticised by other writers, so that his last articles have been mostly polemic. He declares that others have applied the thiosinamin in cases not at all adapted for this drug, hence their failures to obtain results as good as his.

State Boards of Registration

COMING EXAMINATIONS.

Board of Medical Examiners of State of Texas, San Antonio, October 17. Secretary, T. T. Jackson, San Antonio.

State Board of Medical Examiners of New Jersey, Trenton, October 17-18. Secretary, E. L. B. Godfrey, Camden.

State Board of Health of Illinois, The Great Northern Hotel, Chicago, October 18. Secretary, J. A. Egan, Springfield.

Louisiana State Board, New Orleans, October 20-21. Secretary, F. A. Larue, New Orleans.

State Board of Heath of Kentucky, Louisville, October 24. Secretary, J. N. McCormack, Bowling Green.

Wyoming September Report.—Dr. S. B. Miller, secretary of the Wyoming Board of Medical Examiners, reports the written examination, held Sept. 6-8, 1905. The number of subjects examined in was 11; total number of questions asked, 110; percentage required to pass, 75. The total number of candidates examined was 4, of whom 3 passed and 1 failed. Representatives of the following colleges passed:

PASSED.

College.	Year. Grad.	Per Cent.
University of Minnesota	(1904)	82.3
University of Oregon	(1905)	81.4
Ohio Medical University	(1905)	81.8

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending October 7:

Glennan, James D., surgeon, leave of absence extended ten days.

Marrow, Charles E., asst.-surgeon, ordered from Fort Sheridan, Ill., to Chicago, Ill., for temporary duty as attending surgeon and examiner of recruits.

Truby, Albert E., asst.-surgeon, granted leave of absence for one month.

Gapen, Nelson, asst.-surgeon, granted leave of absence for one month, with permission to visit the United States.

Juenemann, George F., asst.-surgeon, granted leave of absence for fifteen days.

Cowper, Harold W., asst.-surgeon, granted leave of absence for one month on surgeon's certificate of disability to take effect on his discharge from treatment at the Army General Hospital, Presidio of San Francisco, Cal.

Williamson, Llewellyn P., asst.-surgeon, resignation of commission accepted to take effect December 15.

Lyster, Theodore C., Wadhams, Sanford H., Robbins, Chandler P., Rhoads, Thomas L., Gilchrist, Harry L., Lyster, William J. L., Persons, Elbert E., Bispham, William N., asst.-surgeons, advanced to rank of captain October 3.

Newlove, George, contract surgeon, left Fort Oglethorpe, Ga., on leave of absence for two months.

Davis, Oscar F., contract surgeon, left Fort DeSoto, Fla., for duty at Jefferson Barracks, Mo.

Ashburn, James K., contract surgeon, returned to Fort Lincoln, N. D., from duty with troops in the field.

Adair, George F., contract surgeon, left Fort Wadsworth, N. Y., and arrived at Sea Girt, N. J., for temporary duty.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending October 7:

Moore, J. M., P. A. surgeon, orders of September 27 modified; ordered to the Navy recruiting rendezvous, New York, N. Y.

Blackburn, T. C., acting asst.-surgeon, detached from duty with naval recruiting party No. 2, and ordered to the naval recruiting rendezvous, St. Louis.

Bradley, G. P., medical director, detached from the Naval Hospital, Washington, D. C., October 15, and ordered to the Navy Yard, Portsmouth, N. H., *and to additional* duty in command of the Naval Hospital at that place.

Dickinson, D., medical director, detached from the Navy Yard, Portsmouth, N. H., and ordered to command the Naval Hospital, Washington, D. C.

Law, H. L., surgeon, retired, detached from the naval recruiting rendezvous, Boston, and ordered home.

McCullough, F. E., surgeon, detached from the *Pensacola* and ordered to the *Albatross.*

Huntington, E. O., surgeon, detached from the *Albatross* and ordered to Washington, D. C., and report at the Navy Department.

Stuart, A., P. A. surgeon, [illegible] from the Naval Hospital, Chelsea, Mass., and ordered t [illegible] additional duty at the Naval Training [illegible]

Michels, R. H., asst.-surgeon, ordered to the Naval recruiting rendezvous, Kansas City, Mo.

Elmore, B., asst.-surgeon, detached from the Naval Hospital, Washington D. C., December 1, and resignation accepted, to take effect same day.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending October 4:

Gassaway, J. M., surgeon, to rejoin station at St. Louis.

Greene, J. B., P. A. surgeon, to proceed to Port Gibson, Miss., and report to Surgeon Guiteras for special temporary duty.

McMullen, John, P. A. surgeon, to proceed to Gulfport, Miss., for instructions relative to special temporary duty at or near Scranton, Miss.

Amesse, J. W., P. A. surgeon, relieved from temporary duty at Cairo, Ill., and directed to proceed to New Orleans, and report to Surgeon J. H. White for special temporary duty.

Berry, T. D., P. A. surgeon, to proceed to Gulfport, Miss., for instructions relative to special temporary duty at or near Scranton, Miss.

McLaughlin, A. J., P. A. surgeon, relieved from duty at Hamburg, Germany. Proceed to Berlin, Germany, for duty.

Collins, G. L., asst.-surgeon, granted leave of absence for one day under paragraph 191 of the regulations.

Stewart, W. J. S., acting asst.-surgeon, leave of absence granted for thirty days from October 1, revoked.

Scott, E. B., pharmacist, granted leave of absence for seven days under paragraph 210 of the regulations.

Hall, L. P., pharmacist, granted leave of absence for two days from September 9, under paragraph 210 of the regulations.

BOARD CONVENED.

Board to meet at Tampa Bay Quarantine Station, October 3, for physical examination of Chief Engineer H. L. Boyd, R. C. S. Detail for the board: Asst.-Surgeon R. E. Ebersole, chairman. Acting Asst.-Surgeon G. H. Altree, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the period from September 30 to October 9:

SMALLPOX—UNITED STATES.

California: Los Angeles, Sept. 16-23, 1 case; San Francisco, 1 case.

Illinois: Chicago, Sept. 23-30, 1 death; Galesburg, Sept. 23-30, 3 cases.

Ohio: Cincinnati, Sept. 22-29, 1 case.

Pennsylvania: Altoona, Sept. 23-30, 1 case.

Washington, Tacoma, Sept. 16-23, 1 case.

SMALLPOX—FOREIGN.

Africa: Cape Town, Aug. 19-26, 1 case.

Brazil: Pernambuco, Aug. 1-15, 215 deaths.

China: Hongkong, Aug. 19-26, 1 case, 1 death; Neuchwang, Aug. 5-12, 3 cases.

Ecuador: Guayaquil, Sept. 5-12, 4 cases.

France: Marseilles, Aug. 1-31, 1 death; Paris, Sept. 8-16, 22 cases, 5 deaths.

Gibraltar: Sept. 3-10, 2 cases.

India: Madras, Aug. 19-25, 8 cases.

Mexico: Dona Cecilia, Sept. 25, 1 case.

Russia: Odessa, Sept. 9-16, 4 cases, 1 death.

Spain: Barcelona, Sept. 1-10, 1 death; Cadiz, Aug. 1-31, 1 death.

YELLOW FEVER—UNITED STATES.

Florida: Brent, Sept. 26, 1 case, 1 death; Pensacola, Aug. 29-Oct. 1, 158 cases, 26 deaths.

Louisiana: Ascension Parish, to Sept. 28, 77 cases, 4 deaths; Assumption Parish, to Oct. 2, 38 cases; Avoyelles Parish, to Sept. 29, 11 cases, 2 deaths; East Baton Rouge Parish, to Sept. 30, 7 cases, 1 death; East Carroll Parish, to Oct. 2, 278 cases, 33 deaths; Iberville Parish, to Oct. 3, 30 cases, 8 deaths; Jefferson Parish, to Oct. 2, 428 cases, 46 deaths; Lafourche Parish, 381 cases, 47 deaths; Madison Parish, 307 cases, 18 deaths; Natchitoches Parish, to Sept. 27, 80 cases, 5 deaths; Orleans Parish, New Orleans, July 21-Oct. 4, 3,083 cases, 398 deaths; Plaquemines Parish, to Oct. 2, 54 cases, 8 deaths; Rapides Parish, to Oct. 3, 24 cases; St. Bernard Parish, 24 cases, 3 deaths; St. Charles Parish, to Sept. 29, 117 cases, 16 deaths; St. John the Baptist Parish, to Sept. 27, 151 cases, 14 deaths; St. Mary Parish, to Oct. 3, 756 cases, 29 deaths; St. Tammany Parish, to Oct. 2, 7 cases, 1 death; Tensas Parish, to Sept. 30, 6 cases; Terrebonne Parish, to Oct. 1, 271 cases, 13 deaths.

Mississippi: Gulfport, Aug. 15-Oct. 1, 90 cases, 2 deaths; Gulf Quarantine, July 22-Sept. 16, 65 cases, 1 death; Hamburg, Sept. 15-Oct. 1, 39 cases, 5 deaths; Mississippi City, Aug. 22-Oct. 1, 65 cases; Moss Point, to Oct. 1, 3 cases; Natchez, 62 cases, 3 deaths; Port Gibson, Sept. 27,-Oct. 1, 4 cases; Rosetta, Oct. 1, 2 cases; Scranton, Sept. 29-Oct.1, 17 cases; Vicksburg, Aug. 30-Oct. 1, 81 cases, 7 deaths.

YELLOW FEVER—FOREIGN.

Guatemala: Zacapa, Sept. 21, 18 to 20 deaths.

Honduras: Chamelicon, Sept. 8, 6 cases; Choloma, 1 case; San Pedro, Sept. 8, 2 cases, 2 deaths.

Mexico: Coatzacoalcas, Aug. 19-26, 2 cases; Vera Cruz, Sept. 9-23, 4 cases, 2 deaths.

CHOLERA—INSULAR.

Philippine Islands: Manila, Aug. 23-25, 21 cases, 17 deaths.

CHOLERA—FOREIGN.

China: Shanghai, Aug. 19-26, present.

India: Bombay, Aug. 31-Sept. 5, 1 death.

Japan: Yokohama, Aug. 13-20; 1 case, 1 death.

PLAGUE—INSULAR.

Philippine Islands: Manila, Aug. 12-19, 1 death.

PLAGUE—FOREIGN.

India: Bombay, Aug. 31-Sept. 5, 43 deaths; Karachi, Aug. 27-Sept. 3, 22 cases, 17 deaths.

Japan: Formosa, Aug. 1-31, 2 cases; 2 deaths.

Society Proceedings

COMING MEETINGS.

New York State Medical Association, New York City, October 16 19.

Medical Society of Virginia, Nofolk, October 24-27.

Hawaiian Territorial Medical Society, Honolulu, November 4.

American Academy of Medicine, Chicago, November 9-10.

Kentucky State Medical Association, Louisville, Oct. 18-20.

AMERICAN ASSOCIATION OF RAILWAY SURGEONS.

Second Annual Meeting, held in Chicago, Oct. 4-6, 1905.

The President, Dr. John E. Owens, Chicago, in the Chair.

The association has three kinds of membership—permanent members, delegates and associate members. The association is cosmopolitan and has members from Canada and Mexico.

Forty papers were read, most of them being freely discussed. One session was taken up in discussing the care of fractures; conservative treatment of compound fractures; wiring as a means of securing the best results in compound fractures of the long bones; direct fixation in fractures; fractures of the vertebral column involving the cord and its treatment; fractures of the spine; Colles' fractures; fractures of the patella and fractures of the leg. An interesting feature of the meeting was a lantern-slide exhibit of anopheles and stegomyia mosquitoes, with remarks on how freight and passengers are handled from the quarantined city, New Orleans, Dr. L. Sexton, New Orleans. The papers presented were of a higher order and more scientific than usual; the various subjects were treated by men with extensive and varied experience.

Officers Elected.

The following officers were elected for the ensuing year: President, Dr. Richard W. Corwin, Pueblo, Colo.; vice-presidents, Dr. J. H. W. Meyer, La Porte, Ind.; Dr. S. L. McCurdy, Pittsburg, Pa.; Dr. Bacon Saunders, Fort Worth, Texas; secretary, Dr. H. B. Jennings, Council Bluffs, Iowa; treasurer, Dr. T. B. Lacey, Council Bluffs, Iowa; editor, Dr. Louis J. Mitchell, Chicago; members of the executive board, Dr. W. S. Hoy, Wellston, Ohio, and Dr. J. R. Hollowbush, Rock Island, Ill.

The time and place of the next meeting are to be decided by the executive board.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Annual Meeting, held in Scranton, Sept. 26-28, 1905.

(Continued from page 1110.)

President, Dr. Adolph Koenig, Pittsburg, in the Chair.

Welcome Addresses.

An address of welcome was delivered by the Hon. Alex. T. Connell, mayor of Scranton, in which he stated that, in his opinion, if the laity would observe the established rules of preventive sanitation and hygiene, epidemics and pestilences would be markedly decreased, and that, while the science of medicine was advancing every year, there was more need for the application of the knowledge already laid down.

Dr. Daniel A. Capwell delivered the address of welcome on behalf of the Lackawanna County Medical Society. He urged on the general practitioner, practicing in a limited field in the country districts, that his work was an important one, and that the Pasteurs and the Listers must have their underworkers. He gave in some detail the evolution of medicine and the work in that direction by Harvey, Jenner, Pasteur, Lister, Roux and others, and urged the necessity of medical organization as a factor for social, professional and financial advancement.

The following delegates from other states were introduced and each made a few remarks: Dr. W. Blair Stewart, Atlantic City, N. J., delegate from the New Jersey State Medical Society; Dr. Richard H. Gibbons, New York, delegate from the New York State Medical Society, and Drs. Everett J. McKnight and Herman G. Howe, Hartford, Conn., delegates from the Connecticut State Medical Society.

Election of Officers.

The following officers were elected: President, Dr. William H. Hartzell, Allentown; vice-presidents, Drs. Morgan J. Williams, Scranton; J. W. Bruner, Bloomsburg; Israel Cleaver, Reading, and George G. Harman, Huntingdon; secretary, Dr. C. L. Stevens, Athens; assistant secretary, Dr. Theodore B. Appel, Lancaster; treasurer, Dr. George W. Wagoner, Johnstown; trustees for three years, Drs. Thomas D. Davis, Pittsburg; George W. Guthrie, Wilkesbarre; George D. Nutt, Williamsport; for two years, Dr. T. M. Livingston, Columbia.

The next annual meeting will be held at Bedford Springs, Sept. 13-15, 1906.

Spinal Analgesia in Shock.

At the meeting of the surgical section Dr. Erasmus V. Swing, Coatesville, the second vice-president, presided. The address in surgery was delivered by Dr. Jonathan M. Wainwright, Scranton, who detailed the results of operations on dogs. The results invariably were that the blood pressure decreased in cases in which spinal analgesia had not been employed, but either increased or remained stationary in cases in which it had been employed. He also referred to clinical cases in which he had been able to demonstrate these same points, which, he felt, showed the value of this remedy in those cases where the danger from shock was great.

The Results of Surgical Treatment of Exophthalmic Goiter.

Dr. B. Farquhar Curtis, New York, prefers thyroidectomy to sympathectomy, having performed 11 operations by the latter method, with two deaths from acute thyroidism, one relapse after nine months, and only one complete cure five years after the operation. He reported three thyroidectomies with good results, and cited among the advantages of this method the fact that the scars are not so high up in the neck, and local anesthesia can be used, and a preliminary ligation should be made.

Focal Diagnosis of Operable Tumors of the Cerebrum.

Dr. Charles K. Mills, Philadelphia, called attention to the advancement made during the last decade, and cited as among the causes of failure in the past difficulty and imperfection in localization, smallness of openings, and the relative imperfections of surgical technic. He divided the cerebrum into the following areas: prefrontal, motor, auditory, midfrontal, parietal and occipital, and stated that the tumor was more apt to develop in the region in control of the upper extremities than of the lower.

Surgery of Operable Lesions of the Cerebrum.

Dr. Charles H. Frazier, Philadelphia, stated that failure is often due to delay. Particularly is this true of Jacksonian epilepsy. Trephining of any kind is liable to produce adhesions. He did not favor silver foil between the dura and the skull, citing a case in which it had produced convulsions, which ceased after the removal of the silver foil. Indiscriminate exploratory craniectomies were not advised, but in cases of infantile encephalitis, if the lesion could not be localized, he felt it to be justifiable. Early diagnosis is now more frequent, the percentage of cases in which the tumor is found is larger, and the mortality is not so high as formerly. These things he attributed largely to better methods of diagnosis and larger openings. In many instances palliative operations are justifiable.

Treatment of Trifacial Neuralgia by Complete Avulsion of the Peripheral Branches of the Trigeminal Nerve.

Dr. Ernest Laplace, Philadelphia, stated that he believed the recurrence in many of these cases after excision of the inferior dental nerve was due to regeneration, illustrating this by the regeneration of nerve growths in other parts of the body. He called attention to the fact that whenever the nerve was twisted or squeezed tightly it would break, and stated that in order that the nerve might be extracted as far as possible he had used a specially curved hemostatic forceps, and by twisting the nerve very slowly, taking as much as a minute or two minutes for a single twist, he was able to extract it almost entire; the whole operation requiring from 12 to 20 minutes.

The first session of the medical section was called to order September 26 by the second vice president, Dr. Walter S. Stewart, Wilkesbarre.

The Nostrum Evil and the Council on Pharmacy.

Dr. Solomon Solis Cohen, Philadelphia, delivered the address in medicine. Therapeutics, he said, must depend on diagnosis, as a matter of course, and diagnosis on pathology. The physician must be thoroughly grounded in the fundamental branches back of pathology, but, after all, it is the question of treatment which occupies the principal portion of attention in connection with the physician's relations with the patient. He deplored the position of the profession toward therapeutics which permits the growth of the nostrum evil. The pages of advertising medical journals offer sure cures for various affections which it should be the physician's duty to know how to manage. All are familiar with the visits of the polite gentleman of comprehensive ability, able to instruct the physician how to treat the sick and to enable him to do so with the samples of the particular firm he represents. This credulity on the part of the profession, Dr. Cohen thought, was based on two elements in medical teaching: the one in the teaching of therapeutics in the medical college; the other in the preliminary education of medical students. He called attention to the valuable work being done by the Council on Pharmacy and Chemistry of the American Medical Association in weeding out a number of fraudulent preparations offered to physicians—and employed by them—and asked that the profession encourage the good work. Regarding medical education, he declared that back of the collegiate degree the man entering on the study of medicine should have a thorough training in the laboratory in physics, in chemistry and in biology. The highly complex organism called man, he stated, was made up of many elements, variously constructed, having complex relations with each other, each one exerting certain influences on all the surrounding elements, the whole bound together in connection with the nervous system. To start at the bedside to study the derangements of this complex organism, and the means by which such derangements could be remedied, Dr. Cohen declared, was as ridiculous as the attempt of the astronomer to study an eclipse of the sun without the basic principles of ordinary arithmetic.

Present and Former Methods of Treating Children.

Dr. L. Emmett Holt, New York, said that the treatment of sick children exhibited two subjects of importance: dietetics and general hygiene. The nutrition of the child should be the first step in treatment. In intestinal disorders he regarded as essential factors evacuance, diet and rest. In the chronic disturbances in children beyond infancy, a careful dietary was, in his opinion, the only treatment giving permanent results. Unless severe lesions were present, the majority of the other measures he considered useless. The neuroses he attributed to impaired nutrition. In pneumonia the greatest effort should be made to put the body into a condition of resistance. The question of fresh air, he believed, was too much ignored. In bronchopneumonia fresh air that is not cold should be received and he has found valuable in treatment the alternate use of two rooms with the air first warmed. His emphasis was on the fact that a better understanding of disease and a broader knowledge of children show that the greatest need is a more scientific and intelligent knowledge of practical dietetics and a better understanding of the condition of health and growth. Of greatest importance in acute and chronic disease, he believed, was the knowledge of how best to preserve the nutrition of the body and thus take advantage of Nature's wonderful power of recuperation in early life.

The Diagnosis of Pneumonia and Empyema in Children, with an Analysis of 200 Cases.

Dr. Alfred Hand, of Philadelphia, referred to certain differences in the chest of a child compared with that of an adult, calling attention especially to the harsh character of the normal breath-sounds, the so-called "puerile" and to the soft character of the bronchial breathing in the child, the latter resembling in intensity the normal broncho-vesicular breathing in adults. He urged frequent examinations of plain, as well as of the doubtful, cases. A small or even large area of consolidation, he stated, might give bronchial breathing and increased vocal resonance, while palpation and percussion showed nothing. Sometimes all of the physical signs might be negative, the diagnosis then resting on fever, increased respiration rate above forty per minute, and leucocytes, the latter serving to differentiate the sickness from typhoid fever. Lumbar puncture might be necessary to exclude meningitis.

The possibility of the development of empyema, he said, should always be borne in mind, as well as the possibility of the presence of pus in the chest without causing fever, displacement of the apex-beat of the heart, absence of vocal fremitus and resonance and bronchial breathing. In an analysis of 200 cases an interesting feature was the greater tendency of the pneumonia to affect the right lung.

DISCUSSION.

Dr. J. P. Crozer Griffith, Philadelphia, opened the discussion of these two papers and was in thorough accord with Dr. Holt. He believed that even a slight modification of milk given the baby to be a very important matter. He advocated the starvation treatment of acute indigestion, and in returning to the milk diet he would err rather on the side of returning too slowly than too promptly. In the management of choreic cases his plan is to put them to bed for rest and quieting of the nervous system. In the treatment of pneumonia he agreed entirely with Dr. Holt, believing the object not to be to cure the pneumonia, but to take care of the baby.

Referring to the paper of Dr. Hand, he believed that the more experience one had with the diagnosis of pneumonia and empyema in children the easier many things become, and, on the other hand, the more difficult. Auscultation and percussion, in his opinion, play a minor part compared with the general symptomatology presented by the baby.

Dr. J. H. McKee, Philadelphia, said that in the diagnosis of empyema he thought the first essential was to be on the lookout for it, and that the nature of the empyema, as well as its presence, should be determined. In the differential diagnosis of pneumonia and empyema he considered that the resistance offered to the pleximeter in percussion of great importance. Experimental puncture he considers of value both diagnostically and prognostically.

(To be continued.)

AMERICAN PUBLIC HEALTH ASSOCIATION.

Proceedings of the Twenty-third Annual Meeting, held in Boston, Sept. 25-29, 1905.

(Continued from page 1111.)

Experiments on Purification of Boston Sewage.

Mr. C. E. A. Winslow and Mr. Earl B. Phelps, Boston, read a paper concerning this work carried on for the past three years. Under the conditions of their experiments, crude Boston sewage has been successfully filtered through a 2-foot bed of sand, having an effective size of 0.12 mm., at a rate of 0.4 million gallons per acre per day, divided into four doses in the 24 hours. Their sand effluents were bright, clear and well purified. The depth of the beds can not safely be reduced below two feet. Preliminary septic treatment for 12 and 24 hours does not improve the effluents obtained by sand filtration, although it makes the care of the surface of the beds somewhat easier.

Crude Boston sewage may be treated on single contact beds of fine stone (one-half inch diameter) at a rate of about 1.2 million gallons per acre per day. The effluent, though only partially purified, is generally stable and could be discharged into water without any tendency to create a nuisance. The beds clog rapidly, and the surface needs much attention. A more practical process is the treatment by the double contract system, in primary beds of two-inch material and secondary beds of half-inch material. Such a combination yields a fairly well purified and stable effluent at a rate, on the combined double system, of about 0.7 million gallons per acre per day with beds six feet deep. Such a system does not clog seriously. Primary beds slowly decrease in capacity, but a portion of the loss may be made good by resting for a period. Preliminary septic treatment enables the beds to maintain a higher capacity, but produces an effluent so difficult to purify that their efficiency is interfered with.

The most practical method of those which they have studied appears to be the treatment of crude sewage in double contact beds.

Industrial Wastes and Their Sanitary Significance.

Mr. Marshall O. Leighton, Washington, D. C., said that though trades wastes have been studied for many years the efforts have been directed toward the recovery of valuable ingredients rather than the treatment of objectionable polluting materials. So successfully has this work been conducted that in some industries the by-products have become more valuable than the original product. Not infrequently the by-product wastes are as objectionable as the original wastes.

The disposal of trades wastes has occupied in this country, a sanitary position secondary to that of sewage disposal. There have been only a few investigations, such as the classic of Kinnicutt and Eddy on acid iron wastes, the investigations of the Massachusetts State Board of Health and the U. S. Geological Survey. The problems afforded by trades wastes are often extremely complex and the study thereof should not be ignored. He classified such wastes as those which are putrescible, those which inhibit the reduction or oxidation of putrescible substances; those which silt up streams and produce obstructions. It is not sufficient to say that probably no industrial waste contains the germs of any disease, and therefore, from a purely pathogenic standpoint, that the relation to sanitation is remote. Unstable organic wastes, such as distillery slops, sulphite pulp liquors, soap liquors and creamery effluents, all produce a condition of putrescibility in streams. While this may not be a menace to health, it is certainly included among those reprehensible features common to modern civilization, which have been turned over to the sanitarian for treatment. As a large proportion of this organic matter is nitrogenous, it provides food for the specific germs of water-borne diseases introduced by sewerage systems during longer periods, and it thereby extends their baneful influence. Such wastes, when discharged in large quantities increase the burden of water filtration systems and in some cases render them inefficient. If sanitarians would be truly successful in their efforts to purify streams they must give their attention to the subject of industrial wastes, and study them with the object of recovering valuable by-products. In so doing they will enlist the co-operation of the commercial and industrial world, which finally and inevitably controls the situation.

The Pollution of Shellfish.

Mr. George A. Soper, Ph.D., New York, stated that it should be more generally known that typhoid fever may be caused by eating oysters and other shellfish which have been grown or immersed in sewage-polluted water. The shellfish industries on the American coast are enormous in extent and value. In some places grave sanitary evils occur. With little exception there is no sanitary supervision over any part of the business of collecting, handling and selling the shellfish. Extensive reforms should be initiated if the public is to be protected against the transmission of typhoid and other enteric diseases which are now disseminated in this way, and the interests of the fishermen and others engaged in the shellfish industry are not to be unnecessarily jeopardized. The nature of these reforms is not a matter of question so much as the method of bringing them about. The remedy proposed is a careful study of the conditions and a wide publication of the principles on which the corrective measures must be based and applied.

Sanitary Analysis Versus Sanitary Inspection.

Mr. R. B. Dole, U. S. Geological Survey, Washington, D. C., drew attention to the value of sanitary survey in regions where the potability of water is in question. Detailed local information generally determines the potability of water better than the data afforded by present analytical methods; therefore boards of health should discontinue the examination of samples of water except those collected in their own study of specific water problems. Funds for water investigation may profitably be expended in the collection of data regarding the natural conditions and industrial and municipal developments which aid in the consideration of water-supply problems. Analytical results and other illustrative material are quoted from a recent investigation of surface waters in Minnesota, conducted jointly by the U. S. Geological Survey and the Minnesota State Board of Health.

Copper Sulphate in Public Water Supplies.

Mr. H. W. Clark, Boston, dealt with some aspects of the use of copper sulphate in public water supplies. Experiments to test the bactericidal action of copper were made at the Lawrence Experiment Station. Comparing the action of other metals with copper, he finds that the bacteria increase more and decrease slower when in contact with copper than when in contact with tin, lead, zinc, iron or aluminum. The effectiveness of the metals in destroying *Bacillus coli* appears to be zinc, iron, copper, tin, aluminum and lead, in the order named.

Experiments on the Storage of Typhoid Infected Water in Canteens.

Mr. Earl B. Phelps, Boston, reported that in practically all his experiments a number of typhoid organisms lived through the 24 hours. The progressive killing of the organisms was rapid at first, decreasing rapidly toward the end of the period. The indications are that the surviving organisms are hardy, and would not be entirely killed by a much longer exposure. The efficiency of the canteen falls off rapidly when in continuous use, even with a comparatively soft water. The value of the canteen in actual practice would, therefore, be conditioned on its being frequently cleaned, preferably with oxalic acid, a practice which would doubtless be neglected in actual field or camp service. The value of the canteen as a disinfecting agent is seriously affected by clay in the water, and is practically destroyed by the use of waters high in alkaline carbonates.

Pathology and Pathogenesis of Smallpox.

Dr. W. T. Councilman, Boston, presented a general consideration of the pathology and pathogenesis of this disease. He discussed the cause, mode of infection, mode of production of exanthema, immunity, secondary infection and concluded with an experimental study of smallpox in monkeys.

The Pathology and Etiology of Human Vaccinia.

Dr. William T. Howard, Jr., Cleveland Ohio, discussed this subject under three heads:

1. MATERIAL AND METHODS.

The material on which this study is based consisted of twenty-three pieces of skin excised from successful vaccinations on twelve men, each of whom was vaccinated in three places at the same time. The vaccinated areas were excised at various periods, from 48 to 168 hours after vaccination. As controls, skin was also excised from three unsuccessful vaccinations. The skin was fixed in Zinker's fluid, cut in paraffin, and sections were stained by various methods, eosin and methylene blue and Borrell's stain giving the best results.

2. PATHOLOGY.

The skin lesions of vaccinia closely resemble those of variola, but are in general rapider and surer. Contrary to the current belief, destruction of the epidermis and the formation of the vesicle are well nigh complete in 48 hours after vaccination. The vesicle at this stage is composed of a reticular meshwork of coarser and finer strands of a hyalin fibrinoid material, formed from degenerated epithelial cells. The meshes of the reticulum contain fluid and fine, granular material, and but few cells. Swelling and reticular regeneration comprise the earliest cytoplasmic changes. Later, larger and smaller hyalin droplets appear and the cells are transformed into hyaline fibrinoid material. Invasion of one epithelial cell by another, a conspicuous occurrence in vaccinia of the rabbit's cornea, is also seen here.

Nuclear degeneration is marked and takes several forms, the earliest being (1) swelling with increased prominence of the reticulum, (2) massing of the chromatin in the center and along the nuclear rim, and (3) wrinkling and retraction of the nuclear rim. Later, the nuclei become condensed and shriveled, and often fragment, with the dispersion of chromatin dust in the cytoplasm and inter-cellular spaces.

Comparatively few blood corpuscles are found in the epidermis at this stage. The internal changes in the corium consist of edema, leucocytic infiltration and swelling and proliferation of endothelium of the blood and lymph vessels. These changes are much more marked than in the corresponding stage of variola.

In the seventy-two-hour lesion all the epithelial cells below the horny layer are necrotic or have disappeared. The spaces of the reticulum are smaller and the strands coarser. In the middle and deeper parts of the lesion fibrin and leucocytes are prominent. The leucocytes are of the large and smaller mononuclear and eosinophilic types. On each side of the original vesicle, early secondary vesicles (analogous to those occurring at the margins of the variola vesicle) are conspicuous. Here the earliest changes in the epithelium may be traced; they are identical with those seen at the margins of the forty-eight-hour lesion. The changes in the corium are still more intense.

From seventy-two hours on, the chief additional changes are (1) condensation of the reticulum into a dense hyaline material, containing broken-down leucocytes, (2) further necrosis of epithelial cells at the margins of the primary vesicle, and (3) persistence of the inflammatory changes in the corium.

The scab or crust is formed by the condensation of the reticulum and exudate of the vesicle. It is thrown off on the renewal of the epidermis, the cells of which proliferate at the margins of the lesion and push their way under the scab.

3. ETIOLOGY OF VACCINIA.

No bacteria were found in any of the lesions. There were found in the early lesions structures corresponding to the primary cytoplasmic stage of *Cytoryctes variolæ*, as described by Councilman and his co-workers and by Howard and Perkins in the early stages of variola and by Tyzzer in vaccinia of the calf and rabbit. There was entire absence of the secondary cytoplasmic and the intranuclear stages of *Cytoryctes variolæ*, which is in accord with Tyzzer's experience in vaccinia of the calf and rabbit. Therefore, we believe that vaccinia of man, the calf and rabbit is caused by the primary cytoplasmic stage of *Cytoryctes variolæ*, which is to be regarded as the asexual cycle of this organism.

(To be continued.)

ASSOCIATION OF HOSPITAL SUPERINTENDENTS.

Seventh Annual Conference, held in Boston, Sept. 26-29, 1905.

The President, Dr. George H. M. Rowe, in the Chair.

The Addresses.

At the first meeting, greetings were extended by Dr. David W. Cheever, the Nestor of Boston physicians, and by Rev. Edward Everett Hale, D.D., to which Dr. Henry M. Hurd, Baltimore responded.

Dr. Cheever briefly reviewed the changes in hospital construction and management as observed by him during the past forty years. He advocated the open-air treatment of tents or piazzas wherever possible and that the superintendent be a physician. The growth of hospitals may be explained by the increase in the apartment houses, destroying real home life in its best sense, and in the constant stream of poor immigrants.

Dr. Hale paid high compliments to the Civil War hospitals, in whose activities he was much associated. The hospital is always a better place for the average person who is ill than the home.

President Rowe, in his annual address, said that Nevada is the only state which has no public, private or ecclesiastical hospital. Income from paying patients is about 43 per cent. of the cost of maintenance. Enlargement of city hospitals should be by branch establishments, simple and inexpensive, to be seen in conjunction with the more perfectly equipped central hospital. Co-operation between the various neighboring hospitals is the demand of the times. A step in this direction is the Massachusetts Round Table of men superintendents and the Association of Nurses.

Sir Henry C. Burdett, K.C.B., London, England, spoke of the influence of Boston in introducing, by its trustees and physicians, the spirit of home life into hospitals. Proper keeping of accounts is very important; $20,000 is the smallest amount which will adequately support a hospital bed, and less sums for this purpose should be discouraged. The great expense incurred in building many hospitals, when not necessary, is deplorable.

The afternoon session included papers by leading architects on hospital construction.

Hospital Expenditures.

Wednesday morning the topic of the session, presided over by **Dr. George P. Ludlam**, was hospital expenditures. The chairman pointed out how rapidly these had increased and agreed that many patients, whose prospects were formerly hopeless, are now cured. But he raised the question whether all of this great increase was justifiable.

Dr. Moses Collins urged the need of courses in hospital construction, economics, etc., in medical schools.

Dr. S. S. Goldwater explained the reasons for much of this increased cost as due to building materials, fire proofing, air space, heating and ventilating. All are necessary nowadays and expensive. Concluding, he urged the value and economy of branch convalescent hospitals.

Dr. Thomas Howell believes in the small hospital. Better physicians and nurses graduate from them. Decorative features should be eliminated from hospital construction.

The afternoon was spent in visiting the hospitals of Boston.

The evening session was held in the Boston Medical Library. The first paper was by **Dr. John M. Hurd** on "John Howard's Observations on Hospitals, 1773-1790," and his emphasis and that of **Dr. Henry C. Burdett**, who followed him, was placed on the need of more sympathetic treatment of consumptives. Ordinary precautions and intelligent co-operation render the domestic treatment of the disease reasonably safe.

Medical Libraries in Hospitals Unnecessary.

"Medical Libraries in Hospitals" were described, using that at the Massachusetts General Hospital as a basis, by **Mrs. Grace Whiting Meyers** and strongly approved by **Dr. George P. Ludlam**. The space can be better used. In the New York Hospital the space once used for a library is now used for a reception room for nurses.

Thursday morning's session was presided over by **Dr. Renwick R. Ross**. The topics discussed were "Multiple-storied Buildings for Hospitals in Cities," by **Dr. A. J. Ochsner**; "Refuse Destroyers and Disinfectants," by **Dr. John H. McCollom**; "Cold Storage and Refrigeration in Hospitals," by **Dr. Ross**; "The Utilization of Hospital Waste," by **Dr. S. A. Washburn**, and "Engine-room Economics," by **Jeremiah C. Long**, chief engineer of the Boston City Hospital.

Hospital Accounts.

The afternoon session, presided over by **Dr. C. Irving Fisher**, was devoted to a discussion of hospital accounts.

Dr. Fisher suggested that there should be some common system of schedules and statistics and that all reports should be arranged on business principles.

Dr. James R. Coddington favored such an arrangement as will permit of comparison of per capita cost in different institutions.

Miss Maud Banfield read a paper on "Hospital Statistical Tables as to Classification of Patients."

American Nurses' Pension Fund Proposed.

The final session was held on Friday morning. A question-box, conducted by **Dr. John M. Peters**, chairman of the session, occupied much of the time.

The only long speech was by **Sir Henry C. Burdett**, K.C.B., who gave an account of the "British National Nurses' Pension Fund," founded by his efforts in 1888 with $300,000 as a start. It now amounts to fully $5,000,000 and, together with annual gifts, makes available a revenue of $450,000 annually. Dr. Burdett stands ready to act in the organization of a similar fund here in America if business men will combine and back him. All English trained nurses contribute in their active days to the fund and all are entitled to care or a pension when incapacitated by illness, accident or disease.

New Officers.

The following officers were elected: President, Dr. George P. Ludlam, of the New York City Hospital; vice-presidents, Dr. Renwick R. Ross, Buffalo; Rev. George C. Hunting, St. Mark's Hospital, Salt Lake City, and Miss Mary L. Keith, Rochester City Hospital; secretary, George R. Bailey, Jr., Jefferson Medical Hospital, Philadelphia; treasurer, Reuben O'Brien, General Hospital, Patterson, N. J.

Buffalo is the place for the next meeting, the date being left with the executive committee.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Eighteenth Annual Meeting, held at New York, Sept. 19-21, 1905.

(Continued from Page 1108.)

Personal Experiences in Myofibroma of the Uterus.

Dr. Miles F. Porter, Fort Wayne, Ind., presented some of the more important facts gained from the treatment and observation of over 125 cases of myofibroma of the uterus. The earlier cases having been seen during a rather exacting general practice, and many of them operated away from home, in private houses, without adequate assistance, accounted for the fact that the records of this part of his work were imperfect. Of the 125 cases, more than 100 were subjected to supravaginal hysterectomy. Two vaginal hysterectomies were done, and in a few cases the tumors were removed by the vagina without opening the peritoneal cavity. No vaginal myomectomies were done in which the abdomen was entered. Myomectomy through the abdomen was done six or eight times only, except cases in which small fibroids were removed during celiotomy for other causes, and these were not considered. Hemorrhage was not so prominent a symptom as was generally thought. In two cases this was the immediate cause of operation, and in one it manifested itself first after establishment of the menopause. Pain, especially during the menstrual period, was the most common symptom. Only one case of pyosalpinx as a complication was seen. In one an eight and one-quarter pound tumor was removed from a four and one-half months' pregnant uterus. Normal labor at term followed, and one child has been born to the mother since without accident. In one case the pregnant uterus was removed for pain, on the theory, which the specimen proved correct, that the woman could neither miscarry nor carry the child to term. The third was operated on because of mild sepsis due to retained fetus. Both recovered.

Women with fibroids are peculiarly liable to infection following labor, miscarriage or menstrual flow. In several cases this danger was the chief indication for operation. Three cases were reported to support this opinion. Rapid growth of fibroids during pregnancy was believed to be more apparent than real. Partial or complete sterility is common in fibroid patients. But one case of malignant degeneration was seen, and only one case died. This was due to the breaking down of a large vaginal tumor, coexisting with a large abdominal tumor. Both were removed through the abdomen. Removal of the vaginal tumor by the vagina by morcellation, and an abdominal hysterectomy later, would probably have saved the patient, who died from the effect of the sepsis from which she was suffering at the time of the operation, combined with the effect of the shock and loss of blood. One case of dermoid of the ovary with multiple fibroids was met with, one practically a pure myoma, and one fibroid of the ovary complicating fibroid of the uterus.

Oöphorectomy for fibroids is not a justifiable operation, as it neither stops the hemorrhage nor the growth of the tumor. The ideal operation for myofibroma will leave the genital tract intact, or as nearly so as possible within reason. The tubes should always be removed when operation renders pregnancy impossible. Healthy ovaries should be left, as should healthy cervices. Whether to operate through the vagina or through the abdomen may be determined before the operation begins, but the details of the technic should be developed as the operation proceeds. In rare cases the elastic ligature is of service. Twice the bladder was cut, but was immediately repaired, and jointly by the U. S. Geological Survey and the Minnesota State Board of Health.

Copper Sulphate in Public Water Supplies.

Mr. H. W. Clark, Boston, dealt with some aspects of the use of copper sulphate in public water supplies. Experiments to test the bactericidal action of copper were made at the Lawrence Experiment Station. Comparing the action of other metals with copper, he finds that the bacteria increase more and decrease slower when in contact with copper than when in contact with tin, lead, zinc, iron or aluminum. The effectiveness of the metals in destroying *Bacillus coli* appears to be zinc, iron, copper, tin, aluminum and lead, in the order named.

Experiments on the Storage of Typhoid Infected Water in Canteens.

Mr. Earl B. Phelps, Boston, reported that in practically all his experiments a number of typhoid organisms lived through the 24 hours. The progressive killing of the organisms was rapid at first, decreasing rapidly toward the end of the period. The indications are that the surviving organisms are hardy, and would not be entirely killed by a much longer exposure. The efficiency of the canteen falls off rapidly when in continuous use, even with a comparatively soft water. The value of the canteen in actual practice would, therefore, be conditioned on its being frequently cleaned, preferably with oxalic acid, a practice which would doubtless be neglected in actual field or camp service. The value of the canteen as a disinfecting agent is seriously affected by clay in the water, and is practically destroyed by the use of waters high in alkaline carbonates.

Pathology and Pathogenesis of Smallpox.

Dr. W. T. Councilman, Boston, presented a general consideration of the pathology and pathogenesis of this disease. He discussed the cause, mode of infection, mode of production of exanthema, immunity, secondary infection and concluded with an experimental study of smallpox in monkeys.

The Pathology and Etiology of Human Vaccinia.

Dr. William T. Howard, Jr., Cleveland Ohio, discussed this subject under three heads:

1. MATERIAL AND METHODS.

The material on which this study is based consisted of twenty-three pieces of skin excised from successful vaccinations on twelve men, each of whom was vaccinated in three places at the same time. The vaccinated areas were excised at various periods, from 48 to 168 hours after vaccination. As controls, skin was also excised from three unsuccessful vaccinations. The skin was fixed in Zinker's fluid, cut in paraffin, and sections were stained by various methods, eosin and methylene blue and Borrell's stain giving the best results.

2. PATHOLOGY.

The skin lesions of vaccinia closely resemble those of variola, but are in general rapider and surer. Contrary to the current belief, destruction of the epidermis and the formation of the vesicle are well nigh complete in 48 hours after vaccination. The vesicle at this stage is composed of a reticular meshwork of coarser and finer strands of a hyalin fibrinoid material, formed from degenerated epithelial cells. The meshes of the reticulum contain fluid and fine, granular material, and but few cells. Swelling and reticular regeneration comprise the earliest cytoplasmic changes. Later, larger and smaller hyalin droplets appear and the cells are transformed into hyaline fibrinoid material. Invasion of one epithelial cell by another, a conspicuous occurrence in vaccinia of the rabbit's cornea, is also seen here.

Nuclear degeneration is marked and takes several forms, the earliest being (1) swelling with increased prominence of the reticulum, (2) massing of the chromatin in the center and along the nuclear rim, and (3) wrinkling and retraction of the nuclear rim. Later, the nuclei become condensed and shriveled, and often fragment, with the dispersion of chromatin dust in the cytoplasm and inter-cellular spaces.

Comparatively few blood corpuscles are found in the epidermis at this stage. The internal changes in the corium consist of edema, leucocytic infiltration and swelling and proliferation of endothelium of the blood and lymph vessels. These changes are much more marked than in the corresponding stage of variola.

In the seventy-two-hour lesion all the epithelial cells below the horny layer are necrotic or have disappeared. The spaces of the reticulum are smaller and the strands coarser. In the middle and deeper parts of the lesion fibrin and leucocytes are prominent. The leucocytes are of the large and smaller mononuclear and eosinophilic types. On each side of the original vesicle, early secondary vesicles (analogous to those occurring at the margins of the variola vesicle) are conspicuous. Here the earliest changes in the epithelium may be traced; they are identical with those seen at the margins of the forty-eight-hour lesion. The changes in the corium are still more intense.

From seventy-two hours on, the chief additional changes are (1) condensation of the reticulum into a dense hyaline material, containing broken-down leucocytes, (2) further necrosis of epithelial cells at the margins of the primary vesicle, and (3) persistence of the inflammatory changes in the corium.

The scab or crust is formed by the condensation of the reticulum and exudate of the vesicle. It is thrown off on the renewal of the epidermis, the cells of which proliferate at the margins of the lesion and push their way under the scab.

3. ETIOLOGY OF VACCINIA.

No bacteria were found in any of the lesions. There were found in the early lesions structures corresponding to the primary cytoplasmic stage of *Cytoryctes variolæ*, as described by Councilman and his co-workers and by Howard and Perkins in the early stages of variola and by Tyzzer in vaccinia of the calf and rabbit. There was entire absence of the secondary cytoplasmic and the intranuclear stages of *Cytoryctes variolæ*, which is in accord with Tyzzer's experience in vaccinia of the calf and rabbit. Therefore, we believe that vaccinia of man, the calf and rabbit is caused by the primary cytoplasmic stage of *Cytoryctes variolæ*, which is to be regarded as the asexual cycle of this organism.

Hunting, St. Mark's Hospital, Salt Lake City, and Miss Mary L. Keith, Rochester City Hospital; secretary, George R. Bailey, Jr., Jefferson Medical Hospital, Philadelphia; treasurer, Reuben O'Brien, General Hospital, Patterson, N. J.

Buffalo is the place for the next meeting, the date being left with the executive committee.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Eighteenth Annual Meeting, held at New York, Sept. 19-21, 1905.

(Continued from Page 1108.)

Personal Experiences in Myofibroma of the Uterus.

Dr. Miles F. Porter, Fort Wayne, Ind., presented some of the more important facts gained from the treatment and observation of over 125 cases of myofibroma of the uterus. The earlier cases having been seen during a rather exacting general practice, and many of them operated away from home, in private houses, without adequate assistance, accounted for the fact that the records of this part of his work were imperfect. Of the 125 cases, more than 100 were subjected to supravaginal hysterectomy. Two vaginal hysterectomies were done, and in a few cases the tumors were removed by the vagina without opening the peritoneal cavity. No vaginal myomectomies were done in which the abdomen was entered. Myomectomy through the abdomen was done six or eight times only, except cases in which small fibroids were removed during celiotomy for other causes, and these were not considered. Hemorrhage was not so prominent a symptom as was generally thought. In two cases this was the immediate cause of operation, and in one it manifested itself first after establishment of the menopause. Pain, especially during the menstrual period, was the most common symptom. Only one case of pyosalpinx as a complication was seen. In one an eight and one-quarter pound tumor was removed from a four and one-half months' pregnant uterus. Normal labor at term followed, and one child has been born to the mother since without accident. In one case the pregnant uterus was removed for pain, on the theory, which the specimen proved correct, that the woman could neither miscarry nor carry the child to term. The third was operated on because of mild sepsis due to retained fetus. Both recovered.

Women with fibroids are peculiarly liable to infection following labor, miscarriage or menstrual flow. In several cases this danger was the chief indication for operation. Three cases were reported to support this opinion. Rapid growth of fibroids during pregnancy was believed to be more apparent than real. Partial or complete sterility is common in fibroid patients. But one case of malignant degeneration was seen, and only one case died. This was due to the breaking down of a large vaginal tumor, coexisting with a large abdominal tumor. Both were removed through the abdomen. Removal of the vaginal tumor by the vagina by morcellation, and an abdominal hysterectomy later, would probably have saved the patient, who died from the effect of the sepsis from which she was suffering at the time of the operation, combined with the effect of the shock and loss of blood. One case of dermoid of the ovary with multiple fibroids was met with, one practically a pure myoma, and one fibroid of the ovary complicating fibroid of the uterus.

Oöphorectomy for fibroids is not a justifiable operation, as it neither stops the hemorrhage nor the growth of the tumor. The ideal operation for myofibroma will leave the genital tract intact, or as nearly so as possible within reason. The tubes should always be removed when operation renders pregnancy impossible. Healthy ovaries should be left, as should healthy cervices. Whether to operate through the vagina or through the abdomen may be determined before the operation begins, but the details of the technic should be developed as the operation proceeds. In rare cases the elastic ligature is of service. Twice the bladder was cut, but was immediately repaired, and

of sufficient strength to be depended on to hold the displaced organs, if securely attached to the aponeurotic tissue, preferably where it is thick near the twelfth rib.

Intestinal Obstruction.

Dr. Lewis C. Morris, Birmingham, Ala., said that delay in operating for the relief of ileus is due to one of two things: (1) Assuming that the diagnosis has been made, the adoption of expectant treatment with the hope that it will relieve the condition or that it will recover spontaneously; or (2) the delay resulting from a failure to make a positive diagnosis.

He reported six cases of intestinal obstruction, and believes that if all such cases could be given the benefit of operation the mortality in this condition would be completely revolutionized. The fact that some cases exist for days and are relieved by operation, leads, in cases in which there is an element of doubt, sometimes to delay in surgical interference until the chances for recovery are materially lessened. Occasionally a positive differential diagnosis is very difficult, but the conditions from which a differentiation can not be positively made are almost invariably equally as imperative in their demand for surgical intervention as would be the existence of an ileus. These conditions were mentioned.

Sudden severe abdominal pain, associated with nausea and vomiting, plus constipation, which does not respond within a few hours to cathartics and stimulating enemata constitute a condition in which the indications for operation are positive. The ability to isolate a distended loop of intestine, the presence of shock and stercoraceous vomiting, go to confirm the diagnosis, but the nature of their presence causes undue delay in operating. The more sudden and violent the storm of symptoms initiating the condition, the more imperative the indications for an early operation. To reiterate, after the diagnosis of ileus has been made, that the adoption of treatment other than surgical, with the hope that it may effect a cure, is utterly unjustifiable, and that procrastination, based on the hope of spontaneous recovery, is absolutely criminal.

Diagnosis.

Dr. John B. Deaver, Philadelphia, endeavored to place the matter of laboratory diagnosis in its proper light, showing that it is after all only one form of diagnosis by pathognomonic symptoms. He tried also to make a plea for the more thorough education of medical students in the principles of physical diagnosis and in the knowledge of the natural history of surgical diseases, while at the same time advocating a postponement of laboratory methods until the former have been completely mastered. He endeavored to show the real danger which, as it seems to him, exists of the modern surgeon degenerating into a mere mechanical appliance subject to the controlling mind and will of the laboratory diagnostician. Yet, while above all things discountenancing haste and carelessness in reaching conclusions, and the judicious resort to the therapeutic test of exploratory operations, he pointed out what seems to him the legitimate fields of exploratory incision.

Appendicitis Complicating Diagnosis and Treatment of Tumors and Pregnancy.

Dr. Rufus B. Hall, Cincinnati, believes that the diagnosis of appendicitis, when associated with pelvic and abdominal tumors, or in the pregnant woman, has not received the attention on the part of the general profession that the subject deserves. He wishes to call attention more forcibly to the early recognition of the cardinal signs of appendicitis in these cases. It is the common supposition on the part of the general profession that when a patient, known to have an abdominal or a pelvic tumor, is taken suddenly ill with pain in the abdomen, that there is something wrong with the tumor and the cardinal signs of appendicitis are ignored or overlooked.

Dr. Hall then discussed the differential diagnosis of appendicitis complicating fibroid tumors of the uterus and ovarian tumors; differential diagnosis of appendicitis complicating tubal disease; differential diagnosis of appendicitis associated with pregnancy; the treatment of appendicitis complicating fibroid tumors and ovarian tumors and tubal disease; also the treatment of appendicitis associated with pregnancy.

Prolonged Abdominal Pregnancy.

Dr. C. A. L. Reed, Cincinnati, reported cases as follows:

1. Extrauterine pregnancy with extraperitoneal development of gestation; operated on fifteen months after conception by marsupialization and terminating in recovery.
2. Extrauterine pregnancy with retroperitoneal development of gestation, operated on by marsupialization eleven months after conception and ending in recovery.
3. Extrauterine pregnancy with development of gestation within the anterior abdominal wall, complicated with uterine fibroids, operated on four years and nine months after conception, ending in recovery.

Dr. Reed's conclusion was that the placenta presents the chief factor of danger in operation on these cases. In instances in which the fetus is already dead, and in which there are not symptoms of sepsis demanding immediate operation, a delay for a few weeks is desirable, as thereby the vascularity of the placenta will be greatly reduced, if not entirely destroyed. One case indicated that it might persist to an embarrassing degree after six weeks. The operation by marsupialization is recommended, as it avoids hemorrhage, facilitates perfect drainage and places all conditions under control. The importance of the yeast ferment in eliminating attached fragments of placental detritus was emphasized.

Observations on the Treatment of Face Presentations.

Dr. Augustus P. Clarke, Cambridge, Mass., said that typical cases of face presentation are not common. Undoubtedly *nearly all* cases of such presentation are originally brow positions, but by some irregular uterine contraction and other incidental factors they change to the character of face presentation. If the *occiput* is *anterior* in face presentation, natural delivery becomes impracticable. Schatz's method for relief by external manipulation has its advantages as an *initial measure*. In dolicho-cephalic cases other methods will be demanded. Podalic version will sometimes be successful. In mento-posterior presentation rotation of the chin should be made toward the symphysis pubis. If the child is not dead, and the case is that of mento-anterior presentation, and impaction is taking place, and the maternal pelvis is not too narrow, forceps may be used with benefit. In a mento-posterior presentation, when the case is seen late and the position of the face can not conveniently be changed, and the child is still alive, symphyseotomy offers the best method of procedure for saving both the mother and the child.

TRI-STATE MEDICAL ASSOCIATION OF ALABAMA, GEORGIA AND TENNESSEE.

Annual Meeting, held in Chattanooga, Tenn., Sept. 26-28, 1905.

Dr. William H. Wilder, Birmingham, Ala., presided on account of the resignation of the president, Dr. Hugh L. Appleton, Gadsden, Ala., by reason of ill health in his family.

The meeting was called to order by Dr. Young L. B. Abernathy, Hill City, Tenn. Hon. A. W. Chambliss, mayor of Chattanooga, welcomed the association on behalf of the city, and Dr. Edward B. Wise on behalf of the Medical Society of Hamilton County and the city of Chattanooga. The first vice-president, Dr. William H. Wilder, Birmingham, responded to the address of welcome.

Papers Presented.

Dr. Thomas G. Miller. Gaylesville, Ala., presented a paper on "Pneumonia and Its Treatment," which evoked spirited discussion. Dr. A. Bennett Cooke, Nashville, Tenn., presented a paper on "Sterile Water Anesthesia," which was very generally discussed, and Dr. William D. Haggard, Nashville, Tenn., reported cases of "Surgical Examples of Gastric Ulcer, Cystic Duct Obstruction, Typhoid Perforation and Enlarged Prostate." Dr. William H. Wilder, Birmingham, read a paper on "Emphysematous Gangrene." Dr. Frank P. Norbury, Jacksonville, Ill., read a paper on "The Use and Abuse of the Rest Treatment." Dr. Matthew C. McGannon, Nashville, Tenn., described "The Treatment of Operative Cases Before a After Operations as Practiced in the Woman's Hospital of t no harm resulted. One case had a hemorrhage from a split of the broad ligament, which occurred the night following the operation, as a result of the patient starting violently during a dream. No trouble from silk as ligatures was experienced, but, because of the evidence against it, catgut was substituted as soon as he learned to sterilize the latter by heat.

The death rate of abdominal operations need not be over 2 per cent., and vaginal operations involving the peritoneal cavity should not be above 1 per cent.

Unusual Dilatation of Cornual Blood Vessels with Rupture Into Uterus.

Dr. Frank F. Simpson, Pittsburg, Pa., reported this interesting case, and stated that apart from their association with neoplasms, vascular changes are not infrequently found when persistent bleeding occurs near the menopause. Arteriosclerosis is rather common; but aneurism, aneurismal varix and varicose veins occurring within the myometrium are rare.

In this instance there was an excessive vascularity of the uterus, with sclerotic arteries and varicose veins. The sclerosis is found in its several forms, varying from a slight nodular infiltration of the intima to complete obliteration. In addition, we have the unusual spectacle of greatly dilated varicose veins, which were the subject of repeated spontaneous rupture with repeated spontaneous closure. In the author's case there was a clinical picture which portrays the perils of this disease in its most serious form. In the well-marked cases that have come under his observation, arteriosclerosis of the uterine vessels has been accompanied by menorrhagia and metrorrhagia, which began between the ages of 38 and 45. They grew more and more pronounced, have resisted medicinal and minor surgical measures, finally endangered life, and have yielded only to hysterectomy. In this case, however, the first symptom was a furious hemorrhage, due to the rupture of a large varicose vein into the uterine cavity. Within two months three other hemorrhages burst on her without warning, and each imperiled her life.

The gross pathologic findings make it clear that without surgical intervention hemorrhage or infection would inevitably have closed the scene within a short while.

Primary Bowel Resection Versus Artificial Anus in Strangulated Hernia.

Dr. John Young Brown, St. Louis, limited himself to a discussion of the surgery of those neglected cases in which, at the time of operation, the intestine found in the hernial sac is so damaged that the operator is forced to resort to one of two procedures—the establishment of an artificial anus or a primary bowel resection.

During the last eighteen months he has operated on seven cases of strangulated hernia; four males, three females. In four the hernia was of the inguinal variety and in three of the femoral type. In all, primary resection was done, followed by a radical operation at the hernial site. Of the seven cases, six recovered, and one died. The oldest patient was 70 years, the youngest 20. The duration of strangulation, longest 57 hours, shortest 9 hours. Amount of gut removed, largest four feet; smallest eight inches. Portion of gut involved small bowel. In each case the condition of the bowel was such as to leave no question concerning the advisability of its removal. In all the resection was done through a supplemental abdominal incision, and the anastomosis was made with the Murphy button. The results obtained he attributes to the careful attention to certain points in the operative technic, a neglect of which he believes has been responsible for the high mortality invariably accompanying the surgical treatment of this condition. He described at length the technic which he employs.

Etiology of Floating Kidney and Nephropexy Therefor.

The president, Dr. Howard W. Longyear, Detroit, discussed this in his presidential address. Dec. 17, 1903, while operating on a young girl 16 years of age for appendiceal disease, he accidentally discovered that the right kidney, which was normally placed, could be easily pulled down and held in a firm position of complete prolapse by making traction on the cecum. This led to further observation on the etiology of displaced, loose or floating kidney, both on the cadaver and on the living subject, and afterward, as a result of those observations, to efforts to devise an operation that should have for its object the retention of the kidney in its normal position, as well as the anchoring of the ascending colon in such a manner as to remedy the prolapse of the cecum, which usually obtains in these cases, so that it should not exert further traction on the kidney and through it on the duodenum and renal vessels. The object of the address is to record the results, though unfinished, of these observations. The fact that the kidney in question could be pulled down and held firmly in this position by traction on the cecum and ascending colon was an indication that there exists a more firm and positive attachment of this viscus to the kidney than is generally believed.

After considering the literature of the subject, Dr. Longyear assumed that the kidney of his patient was pulled down by the adhesion of the peritoneal attachment or mesentery of the colon to the fatty capsule of the kidney, and yet the firmness of the attachment was an apparent contraindication. With the object of testing this point, three cases of floating kidney were operated on. The peritoneal cavity was entered through the usual incision in the loin, the redundant mesentery gathered up and attached to the incision of the fascia close to the twelfth rib at the upper angle of the wound. In the first case of extreme ptosis, having had Dietel's crisis for several years, the ease with which the operation was performed, the amount of slack mesenteric tissue brought out and attached, and the immediate result which it had of entirely replacing the kidney so it could not be pushed down into the abdomen, were very encouraging.

In the second and third cases, however, in both of which the displacement was less pronounced, there was practically no mesentery, such as was present in the first case, so that the peritoneal fixation seemed to promise less. However, while drawing out the peritoneal attachment of the bowel and making efforts to push the bowel down, away from the kidney, it was noticed in both cases that there was a cord-like structure passing downward from the lower pole of the kidney, which prevented the separation of the kidney and the bowel. This was included with the peritoneal tissue and attached with it. Further investigation of the literature failed to enlighten the author as to the presence of any tendinous prolongation from the lower pole of the kidney, so further investigation was made on the cadaver. The dissection on the cadaver was described at length. The whole upper half of the abdominal parietes being incised and turned downward the cecum, ascending colon, with hepatic flexure and kidney on the right side, and part of the descending colon, with splenic flexure and kidney on the left side, were removed, the dissection being made from below upward and the organs removed together in such a manner as not to interfere with their normal attachments to each other. On turning the specimens over, the posterior surface of bowel and kidney on each side showed a similar formation of tendinous attachment to each other. This was *found to be formed by the gathering together* of fine longitudinal fibers from the fibrous network which forms the framework of the fatty capsule. The tendinous ridge, formed by its attachment to the posterior surface of the ascending colon, could be followed easily between the peritoneal reflections down to the margin of the lower peritoneal attachment of the bowel and close to the junction of the ileum—in fact, near the point of the so-called origin in the female subject of the suspensory ligament of the ovary. A specimen illustrating the presence of this phrenocolic ligament was exhibited.

How much of an etiologic factor is this embryologic remnant in the production of displaced kidney? This ligamentous union of the kidney and bowel the author claims is the most important factor in the etiology of nephroptosis.

An operation which he has found the most easy of accomplishment is the fixation of this nephrocolic ligament into the upper angle of the wound without severing it from the colon, and also fastening the redundant mesentery, if it be present, in the lower angle of the wound. The convergence of the framework of the fatty capsule into this ligament makes a structure of sufficient strength to be depended on to hold the displaced organs, if securely attached to the aponeurotic tissue, preferably where it is thick near the twelfth rib.

Intestinal Obstruction.

Dr. Lewis C. Morris, Birmingham, Ala., said that delay in operating for the relief of ileus is due to one of two things: (1) Assuming that the diagnosis has been made, the adoption of expectant treatment with the hope that it will relieve the condition or that it will recover spontaneously; or (2) the delay resulting from a failure to make a positive diagnosis.

He reported six cases of intestinal obstruction, and believes that if all such cases could be given the benefit of operation the mortality in this condition would be completely revolutionized. The fact that some cases exist for days and are relieved by operation, leads, in cases in which there is an element of doubt, sometimes to delay in surgical interference until the chances for recovery are materially lessened. Occasionally a positive differential diagnosis is very difficult, but the conditions from which a differentiation can not be positively made are almost invariably equally as imperative in their demand for surgical intervention as would be the existence of an ileus. These conditions were mentioned.

Sudden severe abdominal pain, associated with nausea and vomiting, plus constipation, which does not respond within a few hours to cathartics and stimulating enemata constitute a condition in which the indications for operation are positive. The ability to isolate a distended loop of intestine, the presence of shock and stercoraceous vomiting, go to confirm the diagnosis, but the nature of their presence causes undue delay in operating. The more sudden and violent the storm of symptoms initiating the condition, the more imperative the indications for an early operation. To reiterate, after the diagnosis of ileus has been made, that the adoption of treatment other than surgical, with the hope that it may effect a cure, is utterly unjustifiable, and that procrastination, based on the hope of spontaneous recovery, is absolutely criminal.

Diagnosis.

Dr. John B. Deaver, Philadelphia, endeavored to place the matter of laboratory diagnosis in its proper light, showing that it is after all only one form of diagnosis by pathognomonic symptoms. He tried also to make a plea for the more thorough education of medical students in the principles of physical diagnosis and in the knowledge of the natural history of surgical diseases, while at the same time advocating a postponement of laboratory methods until the former have been completely mastered. He endeavored to show the real danger which, as it seems to him, exists of the modern surgeon degenerating into a mere mechanical appliance subject to the controlling mind and will of the laboratory diagnostician. Yet, while above all things discountenancing haste and carelessness in reaching conclusions, and the judicious resort to the therapeutic test of exploratory operations, he pointed out what seems to him the legitimate fields of exploratory incision.

Appendicitis Complicating Diagnosis and Treatment of Tumors and Pregnancy.

Dr. Rufus B. Hall, Cincinnati, believes that the diagnosis of appendicitis, when associated with pelvic and abdominal tumors, or in the pregnant woman, has not received the attention on the part of the general profession that the subject deserves. He wishes to call attention more forcibly to the early recognition of the cardinal signs of appendicitis in these cases. It is the common supposition on the part of the general profession that when a patient, known to have an abdominal or a pelvic tumor, is taken suddenly ill with pain in the abdomen, that there is something wrong with the tumor and the cardinal signs of appendicitis are ignored or overlooked.

Dr. Hall then discussed the differential diagnosis of appendicitis complicating fibroid tumors of the uterus and ovarian tumors; differential diagnosis of appendicitis complicating tubal disease; differential diagnosis of appendicitis associated with pregnancy; the treatment of appendicitis complicating fibroid tumors and ovarian tumors and tubal disease; also the treatment of appendicitis associated with pregnancy.

Prolonged Abdominal Pregnancy.

Dr. C. A. L. Reed, Cincinnati, reported cases as follows:

1. Extrauterine pregnancy with extraperitoneal development of gestation; operated on fifteen months after conception by marsupialization and terminating in recovery.
2. Extrauterine pregnancy with retroperitoneal development of gestation, operated on by marsupialization eleven months after conception and ending in recovery.
3. Extrauterine pregnancy with development of gestation within the anterior abdominal wall, complicated with uterine fibroids, operated on four years and nine months after conception, ending in recovery.

Dr. Reed's conclusion was that the placenta presents the chief factor of danger in operation on these cases. In instances in which the fetus is already dead, and in which there are not symptoms of sepsis demanding immediate operation, a delay for a few weeks is desirable, as thereby the vascularity of the placenta will be greatly reduced, if not entirely destroyed. One case indicated that it might persist to an embarrassing degree after six weeks. The operation by marsupialization is recommended, as it avoids hemorrhage, facilitates perfect drainage and places all conditions under control. The importance of the yeast ferment in eliminating attached fragments of placental detritus was emphasized.

Observations on the Treatment of Face Presentations.

Dr. Augustus P. Clarke, Cambridge, Mass., said that typical cases of face presentation are not common. Undoubtedly nearly all cases of such presentation are originally brow positions, but by some irregular uterine contraction and other incidental factors they change to the character of face presentation. If the occiput is anterior in face presentation, natural delivery becomes impracticable. Schatz's method for relief by external manipulation has its advantages as an initial measure. In dolicho-cephalic cases other methods will be demanded. Podalic version will sometimes be successful. In mento-posterior presentation rotation of the chin should be made toward the symphysis pubis. If the child is not dead, and the case is that of mento-anterior presentation, and impaction is taking place, and the maternal pelvis is not too narrow, forceps may be used with benefit. In a mento-posterior presentation, when the case is seen late and the position of the face can not conveniently be changed, and the child is still alive, symphyseotomy offers the best method of procedure for saving both the mother and the child.

TRI-STATE MEDICAL ASSOCIATION OF ALABAMA, GEORGIA AND TENNESSEE.

Annual Meeting, held in Chattanooga, Tenn., Sept. 26-28, 1905.

Dr. William H. Wilder, Birmingham, Ala., presided on account of the resignation of the president, Dr. Hugh L. Appleton, Gadsden, Ala., by reason of ill health in his family.

The meeting was called to order by Dr. Young L. B. Abernathy, Hill City, Tenn. Hon. A. W. Chambliss, mayor of Chattanooga, welcomed the association on behalf of the city, and Dr. Edward B. Wise on behalf of the Medical Society of Hamilton County and the city of Chattanooga. The first vice-president, Dr. William H. Wilder, Birmingham, responded to the address of welcome.

Papers Presented.

Dr. Thomas G. Miller, Gaylesville, Ala., presented a paper on "Pneumonia and Its Treatment," which evoked spirited discussion. Dr. A. Bennett Cooke, Nashville, Tenn., presented a paper on "Sterile Water Anesthesia," which was very generally discussed, and Dr. William D. Haggard, Nashville, Tenn., reported cases of "Surgical Examples of Gastric Ulcer, Cystic Duct Obstruction, Typhoid Perforation and Enlarged Prostate." Dr. William H. Wilder, Birmingham, read a paper on "Emphysematous Gangrene." Dr. Frank P. Norbury, Jacksonville, Ill., read a paper on "The Use and Abuse of the Rest Treatment." Dr. Matthew C. McGannon, Nashville, Tenn., described "The Treatment of Operative Cases Before and After Operations as Practiced in the Woman's Hospital of the

State of Tennessee," and Dr. James T. Searcy, Tuscaloosa, Ala., read a paper on "Medicolegal Insanity."

Election of Officers.

The following officers were elected for the ensuing year: President, Dr. A. Bennett Cooke, Nashville, Tenn.; vice-presidents, Drs. William D. Haggard, Nashville, Tenn.; Albert A. Davidson, Augusta, Ga., and Wellington P. McAdory, Birmingham, Ala.; secretary, Dr. Raymond Wallace, Chattanooga, Tenn., and treasurer, Dr. George R. West, Chattanooga, Tenn. The society will meet next year in Chattanooga.

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.

Fourteenth Annual Meeting, held in Detroit, Sept. 26-28, 1905.

The first vice-president, Lieutenant-Colonel Albert H. Briggs, N. G. N. Y., occupied the Chair, in the absence of the president, Surgeon-General Walter Wyman, United States Public Health and Marine-Hospital Service.

Reports of Officers and Committees.

The annual reports of officers and committees were presented. The secretary reported an increase of nearly 200 in membership; the treasurer a balance of more than $5,000 in the treasury; the chairman of the necrological committee the deaths of 16 members of the association during the year, and the committee on permanent international congress of military surgeons progress.

Entertainment.

The entertainments included an informal reception at the Hotel Cadillac, a tally-ho tour through the city parks and boulevards, a theater party, a trolley excursion to Orchard Lake, Pine Lake and Cass Lake and a trip on the revenue cutter *Tuscarora* to the St. Clair flats, with luncheon at the Marshland Club. September 26 a general reception was held at the Hotel Cadillac, followed by a public meeting at which Hon. George P. Codd, mayor of Detroit, delivered an address of welcome on behalf of the city. In the absence of Senator Russell A. Alger, Representative Denby addressed the meeting on "Michigan in War." Surgeon-General S. Suzuki, imperial Japanese navy, then delivered an address and exhibited lantern slides showing scenes among the sick and wounded in the Russo-Japanese war.

Prize Awarded.

The Enno Sander Prize Model Board of Award reported that no paper has been presented in competition; the Seaman Prize Board of Award reported that it had awarded the Seaman prize of $500 to Major Jefferson R. Kean, U. S. Army, for his paper on "The Prevention of Disease in the Army and the Best Method of Accomplishing That Result."

Major Kean, in this paper, pleaded for the re-establishment of the canteen at Army posts, and sought to show by statistics that venereal disease and other diseases traceable to dissipation have markedly increased in the United States Army since Congress abolished the canteen. He considered the reason for this to be plain, viz., that on the abolition of the canteen at which beer and other comparatively mild liquors were sold under proper restrictions, the soldier who wanted to drink went to the low groggeries which were allowed to be establised outside of each military post, and there he drank bad liquor, and, while under its influence, committed excesses and contracted disease.

Major Kean also made an attack on the cleanliness of Japanese camps, and stated that the only reason why the Japanese suffered less from typhoid fever than the American was because the Japanese used large quantities of tea in the preparation of which the water was necessarily boiled. He also said that there was a possibility of the Japanese being constitutionally immune from typhoid fever.

He commented unfavorably on the volunteer regiments in service during the Spanish-American War, and said that if regulations had been followed there would have been no more deaths in the Army than at an ordinary health resort, instead of the 2,000 fatalities from typhoid fever alone, which he attributed, in a great measure, to the carelessness and thoughtlessness of the volunteer soldiers and to the lack of experience of their officers.

Experiences During the Russo-Japanese Naval War.

Surgeon-General S. Suzuki, surgeon-general Imperial Japanese Navy, read a most interesting and classical paper. He divided his experiences as surgeon-in-chief of the combined fleets serving on board the flag ship *Mikasa* under Admiral Togo, in two parts: (1) The treatment and management of the wounded, and (2) the sanitary arrangement of the combined fleets.

TREATMENT AND MANAGEMENT OF WOUNDED.

Before the fleets left Sasebo, the naval base, he issued orders that aseptic treatment should be adopted in the treatment of the wounded in all battles and that necessary preparations for the adoption of this treatment should be made. He also ordered the employment of conservative surgery, that amputations on board war ships should be avoided so far as possible, and that every preparation should be made for transferring the wounded as soon as possible after the conclusion of engagements to the hospital ship for conveyance to home hospitals. During an engagement complete asepsis is very difficult of attainment. He, however, believed in the immense value of the aseptic treatment of recent wounds, constantly endeavored to combat all the difficulties that stood in the way of this treatment, and demonstrated that his perseverance in that regard had been abundantly rewarded. From February, 1904, to August, 1905, 3,682 casualties occurred in the navy; 1,891 were killed and 1,791 wounded, 117 of whom afterward died. Of the 1,891 deaths, 1,445 were due to shipwrecks caused by submarine mines, and only 563 to wounds received in actual conflict. Of the 1,791 wounded, 647 received wounds requiring hospital treatment, and of these only 32 died. The aseptic methods employed were the same as those in general use.

His experience during the recent war has led him to the conclusion that the proper treatment of the wounded during action must be divided into two stages. At first only the most urgent first-aid methods can be employed, such as the ligature or compression of arteries, the application of splints and the application of gauze pads and bandages. In the second stage, after the action has ceased, the wounded should be brought to the surgery from the places where they have been temporarily bestowed, and relief given. They should then be transferred as soon as possible to the hospital ship. He considers it impracticable to attempt complicated operations in the limited accommodations offered by war ships, except in case of the most urgent necessity.

LOCATION OF SURGERY.

General Suzuki considers that the proper place for the surgery on the battle ship is below the water-line. Care must be taken to provide good light, good ventilation, and, if possible, an elevator for the conveyance of wounded. It is not necessary that the berths for the sick should be near the surgery, for the wounded during the action may be temporarily removed to some place of greater safety, and the berths may be located in any suitable situation on the proper deck above the water-line. In unprotected cruisers the sides of the surgery should be covered with canvass screens, to obviate injury of the bursting of shells, etc., during action. In the temporary surgery steam sterilizers, buckets for the reception of soiled materials and ice boxes should be provided. An operating table may be improvised from the chests which are always to be found on board ship. As the wounded suffer much from thirst, pitchers with long narrow spouts should be furnished as tumblers or glass tubes are too inconvenient for use.

TRANSPORTATION OF WOUNDED.

The ship's complement in the Japanese navy is divided into two portions, for first-aid and ambulance work, the first division comprising clerks, riggers, servants and bandsmen, who receive instruction from the ship surgeon in the bandaging of wounds, the checking of hemorrhage and the carrying of wounded men. The second division, which includes the remainder of the crew, receives instruction as time and opportunity allow. It was found, however, that during the excitement of battle it was impossible to put in practice all the rules and devices in which the crew had been instructed. In about one-third of the cases, first-aid dressing was applied to the wounded, and the men were carried on stretchers to the surgery. In the remainder of the cases the men were picked up as they fell and carried to the surgery in the arms of their comrades. In many cases of slight injuries the dressing was at once applied, and the men went back to their proper stations without coming to the surgery.

DRESSING MATERIALS.

Thanks to the foresight of the authorities, each ship was provided with a stock of dressing material considerably larger than usually issued, and on this account none of the Japanese ships suffered from deficiency of dressings. The new first-aid package for the use of the navy, suggested by Dr. Suzuki, contained four pieces of supplement gauze, 24 inches long and folded in a package 4 inches square. This package is wrapped in Japanese paper, and is placed in a loose bag of stout Japanese paper steeped in the juice of the bitter persimmon. This bag also contains a regularly folded triangular bandage, and is tightly closed with sterilized paste. This package is much more easily opened than was the old package, and the larger size of the gauze pieces was found materially to facilitate the work of dressing. Each surgery should have a pair of large tailor's shears, which are useful in cutting off the clothing of wounded men, also a large number of dressed splints, fenestrated zinc splints, cotton roller bandages 6 or 7 inches wide, changes of operating clothes for the surgeons and attendants, rubber tubes for checking hemorrhage, and a transfusion apparatus for salt solution. Every soldier and sailor carries on his body a small wooden label marked with his name and rank. This is of the greatest value to the surgeon in identification of the living and of the dead.

EYE-SIGHT OF GUNNERS.

In the Japanese service the eyesight of gunners is always examined before action. If any trouble with the vision is found which would interfere with the usefulness of the individual as a gunner, it is treated at once, or if not easily curable, the man is transferred to another station and his position taken by another man with unimpaired eyesight. It was found that the gases and dust which always accompany the firing of great guns irritate the eyes of the gunners and impair their vision, and for this reason every battery is furnished with a supply of 1 per cent. solution of boric acid.

CHARACTER OF WOUNDS.

Wounds inflicted by shell fragments or splinters due to shell explosions present the characteristic of laceration, whether in soft tissues or bony substance. The wound of entrance is generally smaller than that of exit. Few cases of profuse hemorrhage from such wounds were observed. When bones are injured they are usually broken into small fragments. It was found that the wounds caused by small shell fragments generally healed by primary union, but if a fragment of cloth entered the wound there was always danger of suppuration. The number of wounds inflicted on a single individual varied from 1 to more than 100. Contused, lacerated and explosive wounds furnished the great majority of the injuries. Wounds of the head, face and neck were most frequent; wounds of the lower limbs came next, of the upper limbs next, and the burns and scalds followed. There were 716 drowned, and 25 deaths were due to asphyxia.

SANITARY ARRANGEMENTS, DIET AND WATER SUPPLY.

During the war, with the exception of a transient outbreak of dysentery and the prevalence of beri-beri, which was promptly checked by an increase in the nitrogenous element in the ration, the navy was singularly free from disease.

The daily diet consists of biscuit, 6 ounces, or bread, 8 ounces; rice, 12 ounces; crushed barley, 4 ounces; preserved meats, 5 ounces, or fresh meat, 7 ounces; preserved or fresh fish, 5 ounces; dried vegetables, 3 ounces, or fresh vegetables, 15 ounces; tea leaves, ½ dram; roast barley, 1 dram; sugar, 6 drams. The weekly allowance for cooking purposes consists of peas or beans, 2½ ounces; wheat and flour, 2 ounces; sugar, 3½ ounces; soy, 3 ounces; sesame oil, 1 dram; salt, 1½ ounces; fat, 1 ounce; and the supper ration, biscuit, 3½, or bread, 5 ounces; tea, ½ dram; sugar, 4 drams.

The navy has two water-supply ships furnished with apparatus which will distil about 300 tons of water each daily, and has an addition of two water transports with a capacity of 5,000 tons, and auxiliary water carriers. Throughout the war the supply of distilled water was found in all cases to be sufficient.

Personal cleanliness was enjoined by all members of the crew, and before going into action each individual was required to take a bath and to put on clean underclothing. To this, in Dr. Suzuki's opinion, was due in great measure the small proportion of infected wounds.

HOSPITAL SHIPS.

Japan has two specially fitted hospital ships, the *Kobe-Maru* and *Saikio-Maru*, of about 3,000 tons each, and each containing 186 beds, of which 18 are in an isolated ward and 12 reserved for officers. The transfer of patients was not made by bringing the hospital ship alongside of the man-of-war, but was made by steam launches or boats, and it was found that the hammocks of the patients were the most convenient vehicles for transferring them from the ships to the boats. The proper employment of hospital ships entails much thought and consideration from the surgeon-in-chief of the fleets. Excepting in the battle of the Yellow Sea, there was no need of sending the wounded directly from the war ships to the hospital ships, which were always stationed at the base during action. The Russians allowed their hospital ships to accompany their squadrons, but had little opportunity of availing themselves of the service.

On motion, the association voted Surgeon-General Suzuki a vote of thanks for his most interesting paper.

Election of Officers.

At the final session, September 28, the following officers were elected: President, Lieutenant-Colonel Albert H. Briggs, N. G. N. Y., Buffalo, N. Y.; vice-presidents, Brigadier-General Robert M. O'Reilly, surgeon general, U. S. Army, Washington, D. C., Admiral Presley M. Rixey, surgeon general, U. S. Navy, Washington, D. C., and Colonel George Tully Vaughan, assistant surgeon general, U. S. Public Health and Marine-Hospital Service; secretary (re-elected), Major James Evelyn Pilcher, U. S. Army, Carlisle, Pa.; and treasurer (re-elected), Major Herbert A. Arnold, N. G. Pa., Ardmore, Pa.

Buffalo, N. Y., was selected as the next place of meeting.

(*To be continued.*)

CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting, held Aug. 22, 1905.

The President, Dr. Dudley Tait, in the Chair.

Tendon Transplantations for Infantile Hemiplegia.

Dr. S. J. Hunkin showed a boy, 11 years old, who had infantile spastic hemiplegia, with the typical club hand and foot. The hand was strongly pronated and ulnar-flexed, and could only be approximated to the face with its posterior ulnar border. Eight weeks previously the tendon of the pronator radii teres was detached from its insertion, a silk tendon was sutured to it and then passed around the radius posteriorly and fastened under the periosteum at or just below its original insertion. This muscle now acts as a supinator instead of as a pronator, and the boy is able to feed himself with that hand and carry a glass of milk to his mouth. At a later operation the tibialis posticus was divided behind the ankle, the proximal end was passed behind the tibia and fibula to the outer side of the leg, and then subcutaneously to the outer border of the foot and planted with silk under the periosteum at the base of the fifth metatarsal bone. The boy can now dorsi-flex and pronate the foot. Dr. Hunkin called especial attention to the fact that the boy could make these new movements without training as soon as the splint was removed. He now proposes, as a final operation, to move the flexor carpi ulnaris to the position of an extensor; for when the wrist is well extended the hand flexors work to better mechanical advantage.

Diffuse Dilatation of the Esophagus.

Dr. H. C. Moffitt showed a patient who had had difficulty in swallowing for about seven years off and on. The patient knew of no injury to his esophagus. He has the sensation that his food is stopped before it reaches his stomach. It may then return to his mouth or it may produce choking sensations, together with dyspnea and palpitation. More recently he has had cramps under the sternum. He can sometimes assist the passage of food through his esophagus by taking a long breath and throwing his head back. At present a stomach tube can not be passed into the stomach on account of an obstruction that is met about 47 cm. from the teeth. The esophagus will hold about 500 c.c. of liquid, and the material obtained from it recently shows pus and blood cells. After the patient had swallowed a suspension of bismuth a skiagraph was made, and this showed a diffuse spindle-shaped dilatation of the esophagus.

Dr. C. M. Cooper stated that the esophagus normally holds about 100 c.c. of fluid. In the diagnosis of carcinoma of the esophagus it is important to remember that the bronchial glands are frequently the first to be involved, and that their enlargement may be demonstrated by the use of the *x*-ray.

Dr. George Blumer has seen a diffusely dilated esophagus at autopsy. Its walls were very much thickened, resembling those of a congenitally dilated colon.

Leprosy Simulating Syringomyelia.

Dr. H. C. Moffitt presented a boy who had come from Cape Verde Islands about three years ago. No satisfactory history of his present illness could be obtained. The skin showed an irregular pigmentation with somewhat oval or circular whitish patches scattered over it. The latter are not anesthetic and they sweat after injections of pilocarpin. No stigmata of syphilis were found. The left small occipital, right great auricular, and right ulnar nerves are somewhat thickened. The left hand is claw-shaped, with atrophy and the reaction of degeneration in the smaller muscles. There was right equino-varus with atrophy of foot extensors and reaction of degeneration in the tibialis anticus and the peronei. Reflexes were normal, except for the absence of the right Achilles and both plantar reflexes. Irregular anesthesias, especially of the distal portions of the extremities, were present. The differential diagnosis lies mainly between leprosy and syringomyelia. Against the latter are (1) the absence of scoliosis, of ataxia, of involvement of the sphincters, of spasticity of the legs, and (2) the peculiar distribution of the palsies (left hand and right foot), the widespread loss of sensation in the lower extremities and the thickening of the peripheral nerves.

Dr. D. W. Montgomery stated that the skin lesions are such as might occur in leprosy, and that the enlargement of the nerves is very strong evidence in support of that diagnosis.

Dr. H. Morrow said that it is unusual to see so much leucoderma in leprosy without a corresponding loss of sensation.

Dr. C. M. Cooper called attention to the fact that the ulnar nerves may be enlarged in other conditions than leprosy.

Vincent's Angina.

Dr. H. W. Allen demonstrated smears showing the organisms of Vincent's angina. They were obtained from a patient who had had a sore throat, a temperature of 102.6 F. (possibly due to a complicating malaria), and an ulceration on the left tonsil, which was the size of a ten-cent piece and was covered with a grayish-white membrane. The breath possessed a peculiar fetid odor, resembling that of moldy hay. The organisms obtained were a fusiform bacillus and a spirillum. These organisms obtained are believed by Vincent to be the causes of a number of other infections, such as ulcerative stomatitis, noma, gangrene of the lungs, and putrid pleurisy. Clinically the angina must be distinguished from diphtheria and syphilis.

Dr. William Ophüls believes that it is not altogether certain that these organisms cause the angina, for similar ones may be found in the mouths and especially about the teeth, of healthy individuals. It is possible that they are merely secondary invaders, and that the cocci that are almost invariably found in these throats are the primary cause of the lesions. We must differentiate this disease from that recently described by Oliver, which is due to an organism of the oïdium group.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Summer Diarrhea in Infants.

Southworth, in the *Medical Record*, offers suggestions for reducing the prevalence of this disease. Only a small and almost insignificant proportion of the deaths from summer diarrhea occurs in children who have been rightly fed and who enter on the hot months with properly nourished bodies and good digestive powers which have not been overtaxed. The breastfed infant rarely suffers. The large majority of those under one year of age who succumb to these affections are puny, ill-nourished, anemic or rachitic infants, artificially fed, who seem marked for destruction during the first continuous heated term. The child which dies from diarrhea dies as a rule as much because of a previously lowered resistance as from the disease itself. The responsibility rests on the physician whose duty it is to look beyond a present minor ailment and to fortify the infant against this disease. The methods of prevention, fresh air, daily bathing and pasteurization of the food are reasonably familiar to most practitioners, but the truly effective prophylaxis of such mortality should date from the birth of the child. This protection is found in normal breast feeding. The mother should be instructed in the great importance of nursing her own child, and she should likewise be instructed as to how she may best nourish and care for herself in order that she may be able to satisfactorily nourish her babe. In those children not subsisting on breast milk the author recommends beginning early in the spring to protect children against the summer; rachitic children receive proper attention, anemia is treated energetically, diets are regulated, recurrent autointoxication is guarded against, even the slightest subacute or persistent gastrointestinal irregularities are corrected. He lays great stress on the necessity of putting these children on "certified milk." It should be explained to the parent that this milk is not possessed of any sort of charm against summer ills. Certified milk is simply a clean milk instead of a germ and toxin laden one.

It renders no less necessary the careful modification, clean handling, rapid and immediate cooling of the milk, and its maintenance at a low temperature until the food is consumed. The physician should instruct his patient in the kinds of food which young children should have. The practice of early feeding a child stimulants and indigestible foods should be prohibited. Popular beliefs and superstitions, such as the belief that diarrhea is a normal accompaniment of the eruption of the teeth, and that a child is always hungry when it cries, should be overcome. Mothers should be taught that hot weather calls for less food and weaker food, given at longer intervals, with more abundant giving of water. Finally, the author directs attention to other frequent sources of infection. The sucking of the nipple should be absolutely prohibited, "that fraud on infants' credulity, that almost constant appurtenance of the fretful marasmic child, moistened in the bacteria-laden mouth of the attendant to render it more acceptable, dangling against dirty clothes from the dirty string, or reposing temporarily on dusty shelves and tables, carried in dirty pockets, rolling on filthy floors and sidewalks, and then wiped perfunctorily, if at all, before being reinserted in the mouth of the infant." The physician's work is to seek out and correct errors in nutrition, to combat popular misapprehensions, to further the use of clean milk, and to warn mothers that at the very beginning of loose movements in summer they should stop the use of cow's milk in any form, clear out the bowels with castor oil, give water or cereal gruels only, and send promptly for the physician, since delay is so often fatal.

Enuresis.

Barnes, in *American Medicine*, discusses the subject of incontinence of urine in children and states that the successful treatment depends on determining the cause. Enuresis is a symptom of one or more disorders varying from perverted disposition to genuine nervous diseases. The author gives a classification of the causes, both organic and functional, of this condition. Every organ and reflex must be carefully studied. The urine and feces must be repeatedly examined. These children must be kept under observation with diligence and without ceasing. The most important elements in the treatment of this condition are diet, hygiene, habit and training.

DIET.

A generous diet of easily digested food agrees with most children; they should never be overfed. Sometimes a polyuria is associated with an excessive starchy diet, and antidiabetic treatment relieves the condition. In other cases heavy meats and fish have to be eliminated. Stimulating foods and drinks, and liquids of all kinds, should be omitted as much as possible before retiring. In some instances the urine is irritating because of its concentration; in these limiting the liquids would aggravate the enuresis. More frequently the urine is abundant, of low specific gravity, and of almost neutral reaction. Many of these children have chronic intestinal indigestion and must be treated accordingly. Emptying the bowel before retiring is a good practice.

HYGIENE AND HABIT.

Mental and physical irritation should be reduced to a minimum. A quiet, salubrious country place is desirable. Regular habits are imperative. This applies not only to diet, exercise and sleep, but to evacuation of the bowel and bladder. Children should be taught to hold the urine for a considerable time during the day, and should be awakened and made to urinate at a regular hour each night. Exercising in the open air and sunshine is always beneficial. Special exercises directed to strengthening the local muscles can be undertaken with older children. The bath is another hygienic measure often misused. Warm baths are relaxing and frequently followed by colds. The gradually cooling shower or tub bath followed by brisk rubbing, develops vim, vigor and virility. The cold spinal douche gives pleasant results in some instances. A hard bed and moderate covering should always be instituted. Elevation of the foot of the bed and appliances attached to the child to prevent lying on the back are rational measures.

MEDICINAL TREATMENT.

Medical treatment alone is usually negative, unless the enuresis is due to highly acid or irritating urine, or infection and inflammation of the urinary mucosa. Then lithium salicylates, potassium citrate and similar drugs give prompt relief. For the general atonic conditions and weakness of the sphincters, strychnin, quinin and ergot are of first value. Iron and arsenic should be added when needed. Atropin is the drug commonly prescribed. It influences the muscular and reflex activity by lessening the contractile power of the bladder and diminishing the hyperesthesia of the spinal centers. When depending on this drug it must be given, like quinin for malaria; to obtain effects gradually increasing doses should be continued until the enuresis is controlled or the full action of the drug is obtained. The atropin treatment must be pushed for weeks or months, and when a cure is established the dose may be gradually lessened and the drug slowly withdrawn. When masturbation is practiced gelsemium to full physiologic effects may be given alone or with sodium bromid.

Premature Infants.

Morse, in *Am. Jour. Obstet.*, states that two objects are to be attained: to keep the baby alive, and to develop its organism. The infant should be protected from noises, bright lights and unnecessary handling. For the maintenance of animal heat incubators and substitutes for incubators are used. Most incubators may be made to maintain a constant temperature, but none of them provide sufficient pure, fresh, warm air. The best substitute is a crib basket, padded with cotton. The top should be covered with a blanket which reaches just below the baby's neck. The desirable temperature (90 to 95 F.), may be maintained by hot-water bags or bottles, the temperature being taken from the thermometer wrapped in the baby's clothing. The temperature of the room should be from 80 to 85 F. The baby should be oiled every three days, but not washed, and wrapped in a quilted gown with a hood. Absorbent cotton makes a satisfactory substitute for a diaper. The best food for premature babies is breast milk, diluted at first with from one to three parts water. Modified milk with low ingredient percentage is the best substitute for breast milk; 5 c.c. should be given at first at one and a half hour intervals, the amount of milk and the intervals being gradually increased. When the infant is too feeble to take food from a nipple it may be fed with a medicine dropper. When stimulation is indicated one or two drops of brandy, strychnin (1/1000 gr.), and oxygen may be useful. Babies under two pounds usually die. The prognosis is very fair when the weight is over four pounds. A slight elevation of temperature is to be expected; in a subnormal temperature there is danger to the infant. Sudden death may occur without apparent cause, hence it is never safe to consider premature infants out of danger until they are thriving under normal conditions.

Anorexia.

Dr. H. C. Wood recommends for failure of appetite, weak digestion and the general debility from warm weather the following stomachic:

℞. Acidi nitrohydrochlorici (fresh).........ʒii 8|
Aquæ dest...........................℥iss 45|
Strychniæ sulph.....................gr. i |06
Misse et adde
Tincture cardamomi comp.
Tincture gentian comp., āā, q. s.......℥vi 180|
M. Sig.: Dessertspoonful after meals, in water.

Amenorrhea.

Goodell placed great reliance in the "mixture of the four chlorids" for women suffering from amenorrhea due to deprivation and depressing hygienic surrounding.

℞. Hydrargyri chloridi corrosiv..........gr. i |06
Liquoris arsenici chloridi.........m. xlviii 3|
Tincturi ferri chloridi
Acidi hydrochloridi diluti, āā..........ʒiv 16|
Syrupi zingiberis q. s. ad.............℥vi 180|
M. Sig.: Dessertspoonful in water after meals.

Prickly Heat.

The following is recommended for this condition:

℞. Zinci carbonati precip.................ʒiv 16|
Zinci oxidi
Glycerini, āā ....ʒii 8|
Aquæ rosæ ....℥viii 240|
M. Sig.: Apply locally.

Dermatitis Venenata from Poison Ivy.

The following is recommended for this condition:

℞. Sodii hyposulphitis ....℥i 30|
Glycerini ....ʒiv 15|
Aquæ dest q. s. ad....................℥viii 240|
M. Sig.: Keep constantly applied.

Medicolegal

To Have an Exhibition of Means of Treating Tuberculosis.—Chapter 75 of the Resolves of Massachusetts of 1905 authorizes the state board of health, within two years, to cause a public exhibition to be made of the various means and methods used or recommended for treating and preventing tuberculosis, now recognized as a communicable and preventable disease. The said board may expend a sum not exceeding $2,000 in carrying out the provisions of this resolve, and is directed to report to the general court (legislature) on or before the 15th day of January next following said exhibition, and shall accompany its report with any recommendations for legislation which it may deem advisable.

Provides for a Hospital for Lepers.—A resolution was by the legislature of Massachusetts in February, 1 that it favored such action by the congress of the United States as would provide for the establishment of a national hospital or colony for the care and treatment of persons afflicted with leprosy. Copies of this resolution were to be sent to the presiding officers of both branches of congress and also to the senators and representatives in congress from Massachusetts. But later the state legislature passed a law, which appears as Chapter 474 of the Acts of Massachusetts of 1905, providing that the state board of charity, subject to the approval of the governor, shall be authorized to take land by purchase or condemnation, in the name and for the use of the commonwealth, and to erect and maintain thereon a hospital for the custody, care and treatment of persons afflicted with leprosy, and for said purpose may expend a sum not exceeding $50,000.

An Act Relative to Wood Alcohol.—Chapter 220 of the Acts of Massachusetts of 1905 provides that whoever, himself or by his servant or agent, or as the servant or agent of any other person, sells, exchanges or delivers any wood alcohol, otherwise known as methyl alcohol, shall affix to the vessel containing the same and shall deliver therewith a label bearing the words, "Wood Alcohol, Poison," in black letters of uncondensed Gothic type not less than one-fourth of an inch in height. Whoever violates the provisions of this section shall pay a fine of not less than $50 nor more than $200. Section 2. Whoever, himself or by his servant or agent, or as the servant or agent of any other person, sells, exchanges or delivers, or has in his possession with intent to sell, exchange or deliver, any article of food or drink, or any drug intended for internal use, containing any wood alcohol, otherwise known as methyl alcohol, shall be punished by a fine of not less than $200 or by imprisonment for not more than thirty days, or by both such fine and imprisonment.

Must Report Diseases of Eyes of Infants.—Chapter 251 of the Acts of Massachusetts of 1905 amends Section 49 of Chapter 75 of the revised laws of that state requiring a householder to give notice of dangerous diseases by incorporating therein this provision: "Should one or both eyes of an infant become inflamed, swollen and red, and show an unnatural discharge at any time within two weeks after its birth, it shall be the duty of the nurse, relative or other attendant having charge of such infant to report in writing, within six hours thereafter, to the board of health of the city or town in which the parents of the infant reside, the fact that such inflammation, swelling and redness of the eyes and unnatural discharge exist. On receipt of such report, or of notice of the same symptoms given by a physician as provided by the following section, the board of health shall take such immediate action as it may deem necessary in order that blindness may be prevented." Whoever violates the provisions of this section shall be punished by a fine of not more than $100. Section 50, relative to physicians is made with new matter indicated by quotation marks to read: If a physician knows that a person whom he is called to visit is infected with smallpox, diphtheria, scarlet fever or any other disease dangerous to the public health, "or if one or both eyes of an infant whom or whose mother he is called to visit become inflamed, swollen and red, and show an unnatural discharge within two weeks after the birth of such infant," he shall immediately give notice thereof in writing over his own signature to the selectmen or board of health of the town; and if he refuses or neglects to give such notice, he shall forfeit not less than $50 nor more than $200 for each offence.

Duty and Liability Under Contagious-Disease Statute.—The Appellate Court of Indiana, division No. 1, says, in town of Knightstown vs. Homer, that by Section 6718 of Burns' Annotated Statutes of Indiana of 1901 the trustees of each town in that state shall constitute *ex-officio* a board of health for such town, and it is made the duty of such board to "elect a secretary who shall be the health officer of the appointing board," and it is the duty of such board "to protect the public health by the removal of causes of disease when known, and in all cases to take prompt action to arrest the spread of contagious and infectious diseases." Smallpox is an infectious and contagious disease, and, under the statute, it is the duty of the ... board to take immediate and active measures to prevent the spread of this disease among its people. The discovery of a contagious disease like smallpox in a thickly settled community, whether one or more cases, as it seems to the court, creates an immediate necessity for activity on the part of those charged with the duty of preventing its spread, and creates a liability on the part of the town to pay any necessary expense incurred by its health board, or, in the absence of an order of its health board, the expenses incurred by its "health officer," under such an emergency. This was an action against the town to recover, among other things, for damage to property destroyed to prevent smallpox contagion in the town. The property was shown to be of the value of $75 at the time a patient was taken to the plaintiff's home, and worthless at the time destroyed. Thus was presented the question, Did the rule for fixing the amount of damages apply to the value of the property at the time it was discovered that the patient was afflicted with smallpox, or at the time the property was taken by the board of health and destroyed? The patient was in the plaintiff's home not by any act or command of the board of health or its secretary, but he was there at the direction of the plaintiff's husband, and with her consent, and there remained until his death, without request from the plaintiff to any one for his removal. Under these facts, as it seems to the court, the rule for assessing the plaintiff's damages for the property so taken, if the town was liable therefor, should be what the property was worth as there situate at the time it was destroyed. If the rule here announced for the assessment of damages be correct, and the property burned was worthless at the time it was so destroyed, as the plaintiff testified, then there could be no recovery for the item of property, as no damages were proven. Again, the court says that acts for the purpose of preventing the spread of disease are wholly within the jurisdiction of the board of health, and the town can only be made liable when the board acts within the scope of its authority, or for the acts of the secretary of the board when an emergency arises and he is acting within the scope of his authority. Nor does the court think that the plaintiff ought to be allowed for nursing and caring for her child, who was taken with varioloid shortly after the death of the smallpox patient above referred to. It says that there was nothing in the evidence which showed that she was in indigent circumstances, or was not clearly able financially to provide any and all means necessary for the care and attention of her son. She and her son were quarantined in her own home, and, in the absence of a statute making the town liable for such services so rendered by her to her son, the town was not liable.

1. **Desmoid Tumor of the Abdominal Wall.**—Montgomery and Bland report the case of a woman, aged 26, who was operated on for a large desmoid tumor of the abdominal wall. The patient had been married at the age of 19 and had two children. The tumor first appeared seven years before operation, and was observed in the lower portion of the abdomen and on the right side, about the middle and lower thirds of the rectus muscle. The growth increased in size gradually for the first six years of its life, but during the last year it grew very rapidly. The tumor after removal measured 76 cm. in its greater circumference, and 66 cm. in its lesser

circumference. It weighed 19 pounds, and had its origin in the sheath of the right rectus. It was of a pearlish pink color, of dense consistence. Microscopically, it was found to be composed of young connective tissue cells. The blood vessels were numerous, and in many areas the vessel walls seemed to be composed of tumor elements. The authors review briefly the history of desmoid tumors and claim that this is the largest thus far reported. They point out that the tumors usually occur in women, and especially in those who have borne children. The tumors appear frequently after childbirth, and therefore Montgomery and Bland believe that pregnancy and labor have some influence in the production of these growths.

2. See abstract in The Journal, June 3, 1905, page 1801.

3. **Cryoscopy of the Blood and Urine in Nephritis and Uremia.**—Tieken describes the apparatus and technic employed in this work, and reports in detail the result of his observations in over 300 cases of nephritis and allied conditions. He has devoted special attention to uremia, and brings out some interesting facts in relation to it. He concludes that cryoscopy of the urine as usually carried out is of little or no value as an aid to diagnosis in nephritis. Cryoscopy of the blood in nephritis does not show anything abnormal until uremia develops, then there is usually an increase in the molecular concentration, and a corresponding reduction of the freezing point. In several cases these changes in the blood were found before any clinical manifestations of uremia were present. This fall in the freezing point is less marked, or absent, if marked edema or anemia is present. The reduction in the freezing point of the blood seems to correspond with the severity of the disease; that is, in rapidly fatal cases the freezing point is reduced rapidly and to a greater degree than in the mild cases. This fact may aid the physician in making a prognosis as well as in determining the efficiency of treatment. In order to be of the greatest value, it must be done systematically in all cases of uremia, and all disturbing factors must be carefully weighed before drawing any conclusions.

5. **The Vagovisceral Reflexes.**—For clinical purposes, Abrams avails himself of the physiologic fact that the vagus nerve may be subjected to mechanical stimulation by directing the patient to draw the head slowly and forcibly backward. Hypertension of the cervical muscles thus elicited results in inhibiting cardiac action which proves of inestimable service in the differentiation of heart murmurs. The same maneuver enables the physician to recognize an asthmatic lung even in the interparoxysmal period. In the normal individual, when the head is thrown backward and maintained in this position, percussion over the manubrium yields a dull or flat sound, whereas in the asthmatic lung the percussion sound over this region remains unchanged. The latter sign the author refers to as the "tracheal traction test." He finds that by this identical maneuver the lower stomach border may be accurately defined by the dullness supplanting tympanicity by percussion. This taken in conjunction with his "stomach reflex," which causes a recession of the lower border of that organ, enables him to determine the motor power of the stomach as well as the actual lower border of that organ. In other words, after defining the lower border of the stomach by percussion during the time the head is extended, he directs the patient to relinquish extension of the head and proceeds to concuss the Traube area. The difference between the percussional areas obtained after both maneuvers is in direct ratio to the motor power of the organ, which varies in the normal person from 2 to 4 cm. The accuracy of his results has been controlled by the *x*-rays, gastrodiaphane and the conventional methods of determining the lower stomach border.

8. **Appendicitis in Children.**—Dowd believes that the peculiarities of appendicitis in children are sufficient to call for special attention. He divides these cases in children into three groups: Early cases in which operations come within the first forty-eight hours; later active cases in which the operations come in the progressive or retrogressive stage; and the interval cases in which operations come after the inflammation has subsided. Dowd states that the percentage of more severe grades of appendicitis is greater in children than in adults, but that children are more likely to recover from severe peritonitis. He sums up the peculiarities of this disease in children as follows: (1) The rapidity and insidiousness of the disease are much greater; (2) the percentage of diffuse and general peritonitis is greater, probably because the omentum is less apt to close the inflamed appendix; (3) the pain is almost always present, but is more difficult to interpret; (4) the vomiting is nearly always present, and is frequently many times repeated; (5) the abdominal palpation, in the majority of cases, is as satisfactory or more satisfactory than in adults, but in a few cases it is absolutely misleading; (6) constipation is much less likely to be present; (7) they have a greater ability to deal with general peritonitis than adults do; (8) during the acute stage of the disease delay is more dangerous than in adults because of the insidious course of the disease and the greater tendency to peritonitis, and immediate operation is to be advised.

10. **Prevention of Ophthalmia in the Newborn.**—Edgar states that no measure should be neglected which can assist in preventing the occurrence of ophthalmia neonatorum. From the standpoint of the obstetrician, he says, there are two means at command for reducing the frequency, if not of practically preventing the occurrence of this condition. These are: First, the antepartum preparation of the maternal passages in cases in which infection is suspected; second, the dropping into each conjunctival sac immediately after delivery of some antiseptic, such as nitrate of silver. Edgar states that he has every faith in Crede's method for the prevention of ophthalmia neonatorum, and that he uses it in both hospital and private cases. He says that after repeated experiments he has found that neither argyrol nor protargol compare with a 2 per cent. solution of silver nitrate for this purpose. Solutions of less strength in his experience do not destroy bacteria, and although solutions of 3 per cent. are harmless they are apt to cause silver catarrh and are not necessary.

14. **The Student Life.**—Dr. Osler said that there are unmistakable signs whereby the genuine student may be distinguished—an absorbing desire to know the truth, an unswerving steadfastness in its pursuit, and an open heart free from suspicion, guile and jealousy. He said that truth is a very simple matter if each one starts with the desire to get as much as possible. No human being is constituted to know the whole truth and nothing but the truth; and even the best of men must be content with fragments, with partial glimpses, never the full fruition. Osler said that the student must remember that his education does not end when he receives a degree and leaves his school or college; to be successful he must remain a student all his life. He said that the *dilettante* is abroad in the land, the man who is always starting tasks and never finishing them, and while many things are studied, few are studied thoroughly. He emphasized the fact that concentration is the price that the modern stu-

that it favored such action by the congress of the United States as would provide for the establishment of a national hospital or colony for the care and treatment of persons afflicted with leprosy. Copies of this resolution were to be sent to the presiding officers of both branches of congress and also to the senators and representatives in congress from Massachusetts. But later the state legislature passed a law, which appears as Chapter 474 of the Acts of Massachusetts of 1905, providing that the state board of charity, subject to the approval of the governor, shall be authorized to take land by purchase or condemnation, in the name and for the use of the commonwealth, and to erect and maintain thereon a hospital for the custody, care and treatment of persons afflicted with leprosy, and for said purpose may expend a sum not exceeding $50,000.

An Act Relative to Wood Alcohol.—Chapter 220 of the Acts of Massachusetts of 1905 provides that whoever, himself or by his servant or agent, or as the servant or agent of any other person, sells, exchanges or delivers any wood alcohol, otherwise known as methyl alcohol, shall affix to the vessel containing the same and shall deliver therewith a label bearing the words, "Wood Alcohol, Poison," in black letters of uncondensed Gothic type not less than one-fourth of an inch in height. Whoever violates the provisions of this section shall pay a fine of not less than $50 nor more than $200. Section 2. Whoever, himself or by his servant or agent, or as the servant or agent of any other person, sells, exchanges or delivers, or has in his possession with intent to sell, exchange or deliver, any article of food or drink, or any drug intended for internal use, containing any wood alcohol, otherwise known as methyl alcohol, shall be punished by a fine of not less than $200 or by imprisonment for not more than thirty days, or by both such fine and imprisonment.

Must Report Diseases of Eyes of Infants.—Chapter 251 of the Acts of Massachusetts of 1905 amends Section 49 of Chapter 75 of the revised laws of that state requiring a householder to give notice of dangerous diseases by incorporating therein this provision: "Should one or both eyes of an infant become inflamed, swollen and red, and show an unnatural discharge at any time within two weeks after its birth, it shall be the duty of the nurse, relative or other attendant having charge of such infant to report in writing, within six hours thereafter, to the board of health of the city or town in which the parents of the infant reside, the fact that such inflammation, swelling and redness of the eyes and unnatural discharge exist. On receipt of such report, or of notice of the same symptoms given by a physician as provided by the following section, the board of health shall take such immediate action as it may deem necessary in order that blindness may be prevented." Whoever violates the provisions of this section shall be punished by a fine of not more than $100. Section 50, relative to physicians is made with new matter indicated by quotation marks to read: If a physician knows that a person whom he is called to visit is infected with smallpox, diphtheria, scarlet fever or any other disease dangerous to the public health, "or if one or both eyes of an infant whom or whose mother he is called to visit become inflamed, swollen and red, and show an unnatural discharge within two weeks after the birth of such infant," he shall immediately give notice thereof in writing over his own signature to the selectmen or board of health of the town; and if he refuses or neglects to give such notice, he shall forfeit not less than $50 nor more than $200 for each offence.

Duty and Liability Under Contagious-Disease Statute.—The Appellate Court of Indiana, division No. 1, says, in town of Knightstown vs. Homer, that by Section 6718 of Burns' Annotated Statutes of Indiana of 1901 the trustees of each town in that state shall constitute *ex-officio* a board of health for such town, and it is made the duty of such board to "elect a secretary who shall be the health officer of the appointing board," and it is the duty of such board "to protect the public health by the removal of causes of disease when known, and in all cases to take prompt action to arrest the spread of contagious and infectious diseases." Smallpox is an infectious and contagious disease, and, under the statute, it is the duty of the town board to take immediate and active measures to prevent the spread of this disease among its people. The discovery of a contagious disease like smallpox in a thickly settled community, whether one or more cases, as it seems to the court, creates an immediate necessity for activity on the part of those charged with the duty of preventing its spread, and creates a liability on the part of the town to pay any necessary expense incurred by its health board, or, in the absence of an order of its health board, the expenses incurred by its "health officer," under such an emergency. This was an action against the town to recover, among other things, for damage to property destroyed to prevent smallpox contagion in the town. The property was shown to be of the value of $75 at the time a patient was taken to the plaintiff's home, and worthless at the time destroyed. Thus was presented the question, Did the rule for fixing the amount of damages apply to the value of the property at the time it was discovered that the patient was afflicted with smallpox, or at the time the property was taken by the board of health and destroyed? The patient was in the plaintiff's home not by any act or command of the board of health or its secretary, but he was there at the direction of the plaintiff's husband, and with her consent, and there remained until his death, without request from the plaintiff to any one for his removal. Under these facts, as it seems to the court, the rule for assessing the plaintiff's damages for the property so taken, if the town was liable therefor, should be what the property was worth as there situate at the time it was destroyed. If the rule here announced for the assessment of damages be correct, and the property burned was worthless at the time it was so destroyed, as the plaintiff testified, then there could be no recovery for the item of property, as no damages were proven. Again, the court says that acts for the purpose of preventing the spread of disease are wholly within the jurisdiction of the board of health, and the town can only be made liable when the board acts within the scope of its authority, or for the acts of the secretary of the board when an emergency arises and he is acting within the scope of his authority. Nor does the court think that the plaintiff ought to be allowed for nursing and caring for her child, who was taken with varioloid shortly after the death of the smallpox patient above referred to. It says that there was nothing in the evidence which showed that she was in indigent circumstances, or was not clearly able financially to provide any and all means necessary for the care and attention of her son. She and her son were quarantined in her own home, and, in the absence of a statute making the town liable for such services so rendered by her to her son, the town was not liable.

1. **Desmoid Tumor of the Abdominal Wall.**—Montgomery and Bland report the case of a woman, aged 26, who was operated on for a large desmoid tumor of the abdominal wall. The patient had been married at the age of 19 and had two children. The tumor first appeared seven years before operation, and was observed in the lower portion of the abdomen and on the right side, about the middle and lower thirds of the rectus muscle. The growth increased in size gradually for the first six years of its life, but during the last year it grew very rapidly. The tumor after removal measured 76 cm. in its greater circumference, and 66 cm. in its lesser

circumference. It weighed 19 pounds, and had its origin in the sheath of the right rectus. It was of a pearlish pink color, of dense consistence. Microscopically, it was found to be composed of young connective tissue cells. The blood vessels were numerous, and in many areas the vessel walls seemed to be composed of tumor elements. The authors review briefly the history of desmoid tumors and claim that this is the largest thus far reported. They point out that the tumors usually occur in women, and especially in those who have borne children. The tumors appear frequently after childbirth, and therefore Montgomery and Bland believe that pregnancy and labor have some influence in the production of these growths.

3. **Cryoscopy of the Blood and Urine in Nephritis and Uremia.**—Tieken describes the apparatus and technic employed in this work, and reports in detail the result of his observations in over 300 cases of nephritis and allied conditions. He has devoted special attention to uremia, and brings out some interesting facts in relation to it. He concludes that cryoscopy of the urine as usually carried out is of little or no value as an aid to diagnosis in nephritis. Cryoscopy of the blood in nephritis does not show anything abnormal until uremia develops, then there is usually an increase in the molecular concentration, and a corresponding reduction of the freezing point. In several cases these changes in the blood were found before any clinical manifestations of uremia were present. This fall in the freezing point is less marked, or absent, if marked edema or anemia is present. The reduction in the freezing point of the blood seems to correspond with the severity of the disease; that is, in rapidly fatal cases the freezing point is reduced rapidly and to a greater degree than in the mild cases. This fact may aid the physician in making a prognosis as well as in determining the efficiency of treatment. In order to be of the greatest value, it must be done systematically in all cases of uremia, and all disturbing factors must be carefully weighed before drawing any conclusions.

5. **The Vagovisceral Reflexes.**—For clinical purposes, Abrams avails himself of the physiologic fact that the vagus nerve may be subjected to mechanical stimulation by directing the patient to draw the head slowly and forcibly backward. Hypertension of the cervical muscles thus elicited results in inhibiting cardiac action which proves of inestimable service in the differentiation of heart murmurs. The same maneuver enables the physician to recognize an asthmatic lung even in the interparoxysmal period. In the normal individual, when the head is thrown backward and maintained in this position, percussion over the manubrium yields a dull or flat sound, whereas in the asthmatic lung the percussion sound over this region remains unchanged. The latter sign the author refers to as the "tracheal traction test." He finds that by this identical maneuver the lower stomach border may be accurately defined by the dullness supplanting tympanicity by percussion. This taken in conjunction with his "stomach reflex," which causes a recession of the lower border of that organ, enables him to determine the motor power of the stomach as well as the actual lower border of that organ. In other words, after defining the lower border of the stomach by percussion during the time the head is extended, he directs the patient to relinquish extension of the head and proceeds to concuss the Traube area. The difference between the percussional areas obtained after both maneuvers is in direct ratio to the motor power of the organ, which varies in the normal person from 2 to 4 cm. The accuracy of his results has been controlled by the x-rays, gastrodiaphane and the conventional methods of determining the lower stomach border.

8. **Appendicitis in Children.**—Dowd believes that the peculiarities of appendicitis in children are sufficient to call for special attention. He divides these cases in children into three groups: Early cases in which operations come within the first forty-eight hours; later active cases in which the operations come in the progressive or retrogressive stage; and the interval cases in which operations come after the inflammation has subsided. Dowd states that the percentage of more severe grades of appendicitis is greater in children than in adults, but that children are more likely to recover from severe peritonitis. He sums up the peculiarities of this disease in children as follows: (1) The rapidity and insidiousness of the disease are much greater; (2) the percentage of diffuse and general peritonitis is greater, probably because the omentum is less apt to close the inflamed appendix; (3) the pain is almost always present, but is more difficult to interpret; (4) the vomiting is nearly always present, and is frequently many times repeated; (5) the abdominal palpation, in the majority of cases, is as satisfactory or more satisfactory than in adults, but in a few cases it is absolutely misleading; (6) constipation is much less likely to be present; (7) they have a greater ability to deal with general peritonitis than adults do; (8) during the acute stage of the disease delay is more dangerous than in adults because of the insidious course of the disease and the greater tendency to peritonitis, and immediate operation is to be advised.

10. **Prevention of Ophthalmia in the Newborn.**—Edgar states that no measure should be neglected which can assist in preventing the occurrence of ophthalmia neonatorum. From the standpoint of the obstetrician, he says, there are two means at command for reducing the frequency, if not of practically preventing the occurrence of this condition. These are: First, the antepartum preparation of the maternal passages in cases in which infection is suspected; second, the dropping into each conjunctival sac immediately after delivery of some antiseptic, such as nitrate of silver. Edgar states that he has every faith in Crede's method for the prevention of ophthalmia neonatorum, and that he uses it in both hospital and private cases. He says that after repeated experiments he has found that neither argyrol nor protargol compare with a 2 per cent. solution of silver nitrate for this purpose. Solutions of less strength in his experience do not destroy bacteria, and although solutions of 3 per cent. are harmless they are apt to cause silver catarrh and are not necessary.

14. **The Student Life.**—Dr. Osler said that there are unmistakable signs whereby the genuine student may be distinguished—an absorbing desire to know the truth, an unswerving steadfastness in its pursuit, and an open heart free from suspicion, guile and jealousy. He said that truth is a very simple matter if each one starts with the desire to get as much as possible. No human being is constituted to know the whole truth and nothing but the truth; and even the best of men must be content with fragments, with partial glimpses, never the full fruition. Osler said that the student must remember that his education does not end when he receives a degree and leaves his school or college; to be successful he must remain a student all his life. He said that the *dilettante* is abroad in the land, the man who is always starting tasks and never finishing them, and while many things are studied, few are studied thoroughly. He emphasized the fact that concentration is the price that the modern student

pays for success, and that thoroughness is the most difficult habit to acquire, though it is the pearl of great price, worth all the worry and trouble of the search. He advised the student to divide his time between books and men, and to thank the stars if they had given him the proper sense to appreciate the inconceivably droll situations which will come to his notice at times. He advised the young graduate to take a good weekly and monthly journal and to read them carefully, and advised him to take postgraduate work every few years. He warned against the danger of prosperity and its inducement to idleness, and he advised keeping out of politics. He concluded by saying that to each one the practice of medicine will be very much as he makes it—to one a worry, a care, a perpetual annoyance; to another, a daily joy and a life of as much happiness and usefulness as can well fall to the lot of man. In the student spirit can best be fulfilled the high mission of our noble calling—in humility, conscious of weakness, while seeking strength; in confidence, knowing the power, while recognizing the limitations of art; in pride in the glorious heritage from which the greatest gifts to man have been derived; and in sure and certain hope that the future holds still richer blessings than the past.

20. Failures in Ophthalmic Practice.—Gould sets forth fifteen reasons for failures to relieve the common systemic results or reflexes of eyestrain: (1) The want of a single good refraction school in the world. Instead of ophthalmology, being as Helmholz said, the most accurate and scientific of the departments of medicine, he thinks it the most inaccurate and unscientific; and this is due to the lack of systematic and adequate training in the difficult art of refraction. (2) Bad case recording, omitting the life history of the patient's ailments, or "the biographic clinic," leaves the cure or non-cure unknown or indefinite. (3) The inexperience, ignorance or impertinence of the optician, incapable of doing his proper work, and aspiring to be an oculist, also prevents good results. (4) Changes in the patient's refraction, not followed by retesting and changes in glasses are another source of failure. (5) Incorrect diagnosis of ametropia is the most frequent cause of failure. (6) The presence of head-tilting often causes an inexact placing of the axis of astigmatism. (7) The morbid writing posture, coupled with its result, lateral spinal curvature, continue the consequences of eyestrain. (8) Non-allowance for the patient's personal equations may frequently account for non-success. (9) Tenotomy for heterophoria does not cure the cause of the heterophoria, which is ametropia. (10) Ascription of the morbid symptoms to general disease will not end in cure if they are due to neglected eyestrain. (11) Subnormal accommodation is far more frequently present than is suspected, and distance correction of the ametropia alone will not give relief. (12) "Hysteria" often caused by eyestrain may persist, when chronic, although the eyestrain has been neutralized. (13) Patients living at a distance because they can not be watched closely are likely to prove "failures." (14) Despair of curing in an obstinate case may lead to too speedy renunciation of effort. (15) The secondary results of long-continued eyestrain may be too chronic or deep seated to cure at once or to cure at all. Despite all these reasons, however, it is contended that in no department of medicine are the cures so near 100 per cent., so speedy or so gratifying as in skilled refraction work.

21. The Technic of Abdominal Section.—Lewis advocates, in abdominal operations, the use of an incision large enough to enable the operator to see what he is doing; he secures perfect hemostasis throughout the operation; he turns in all surfaces so that only smooth peritoneum is left at the end of the operation; in pus cases removal of the source should be carried out at once, without unnecessarily prolonging the operation and endangering the patient's life. He uses sterile catgut for sutures instead of silk. After operation, he says, no opium should be given and as little anodyne as possible. The bowels should be moved early by calomel and enemata, and thirst relieved by salt solution by rectum. Uterosuspension he disapproves of, since the symptoms are referable to metritis and other conditions, which should be relieved when the prolapsus or retroversion will be cured. In suppurations one should open and drain, but not make the operation any more severe than is necessary, as the patient's strength is easily exhausted. Through drainage may be established through the vagina. Suppuration in peritonitis requires drainage, and irrigation is of value. In cases of rupture of the bowel or traumatism the wound should be closed at once with a Lembert suture, the edges well turned in. When a part of the gut must be removed the author prefers closure of the ends and a lateral anastomosis. In ruptured ectopic gestation the sooner the abdomen is opened the better. The Cesarean section should be used more frequently for contracted pelves, etc. Small fibroids should be enucleated and for large or multiple one supravaginal amputation is to be preferred.

25 *Some of the More Unusual Forms of Epilepsy. W. P. Spratling, Sonyea, N. Y.

25. The More Unusual Forms of Epilepsy.—Spratling states that the days of speaking of epilepsy are gone, now we speak of the epilepsies. He says that while the general conception of the disease is the grand mal form, there are enough of the milder varieties to deserve consideration, and it is important that they be understood. He states that some neurologists do not believe in the psychic epileptic equivalent, and that in all probability it never exists as a separate entity, but is always associated in some degree with an attack so mild as to be unrecognizable except under close observation. Nocturnal epilepsy may give rise the next day to mental confusion that may be mistaken for the epileptic equivalent, and the only way to satisfy ourselves that this is not the case is to have the patient watched carefully during the night. The epileptic equivalent state, Spratling declares, is in reality an acute insanity, during which the patient unconsciously may be guilty of any crime. He calls attention to the importance of this from a medicolegal standpoint, and says that the welfare of the patient demands that he receive the same watchful treatment demanded by the acutely insane.

32 Currents of High Frequency from a Static Machine. F. De Kraft, New York.

31. Pleurisy and Tuberculosis.—Von Ruck reviews briefly the salient points which permit of *practical* deductions, and summarizes them as follows:

1. The pleural cavities are readily accessible to bacterial invasion.
2. The great majority of pleurisies with effusion which occur in otherwise healthy individuals are due to infection with tubercle bacillus. This is proved by autopsy findings, by methods of exact diagnosis and by the subsequent clinical histories of the majority of persons who have been the subjects of such attacks.
3. There is ample evidence to indicate that the so-called idiopathic, dry pleurisies are likewise *usually tuberculous.*
4. The subjective symptoms of inflammation of the pleural apices often simulate those of myalgia or rheumatism.
5. In every case of pleurisy, or of persistent pain in the chest or shoulder, which can not be satisfactorily ascribed to other causes, tuberculosis should be suspected and a careful physical examination should be instituted to determine, if possible, the existence of a tuberculous process in the lungs, or elsewhere.
6. Even if physical examination in such cases proves negative, the patient should be regarded as tuberculous until the contrary is proved, and should at least be kept under prolonged observation and re-examined from time to time.
7. The tuberculin test may be relied on to confirm or to exclude the tuberculous nature of pleurisy in case of doubt.
8. The application of these principles will often lead to an earlier recognition of tuberculous disease of the lungs especially, and to the institution of treatment at a period which will in many cases secure to the patient most important advantages in his prospects for recovery.

39. **Dry Iodin Catgut.**—Moschocowitz has devised a modification of the Claudius method of preparing catgut which does not diminish the tensile strength of the catgut. The catgut is removed from the iodin solution at the end of eight days, and thereafter is kept dry and ready for use in a sterile vessel. Clinical work and experiments with this suture material so prepared demonstrated that it is absolutely sterile; that it is impossible to infect it by ordinary means, and that it does not contain sufficient iodin to act as an irritant on the tissues. Its tensile strength is superior to raw catgut and to that prepared by the sublimate-alcohol method. It is easily and cheaply prepared, and it is absorbed only after it has served the purposes for which it is intended.

40. **Dentigerous Cyst of Lower Jaw.**—At the age of 16 years, Barrie's patient first noticed a lump, the size of a small marble, below the lower left canine tooth, which slowly and gradually increased in size until a year ago, since which time it has rapidly enlarged. The canine tooth gradually became displaced, and lay horizontally on the enlarged alveolar border. The swelling extended from the anterior border of the masseter muscle on the right side to the angle of the jaw on the left. The skin was not inflamed. The man was unable to open his mouth beyond the space of 3 cm., and could not masticate any food. A mesial incision was made from the mucocutaneous border of the lip to the hyoid bone. The separation of the tissues disclosed an ugly looking necrotic cavity. The periosteum and bone substance on the anterior aspect of the mandible above, from the alveolar margin to the protuberentia mentalis below, and laterally so far as the tissues of the wound could be extended on either side, showed complete destruction of periosteum and bone. Sufficient room not being obtainable by the mesial incision, the lip was cut through, and lateral incisions were made below the chin, to the anterior borders of the masseter muscles on either side from the median incision, and the flaps reflected. The mylohyoideus, geniohyoideus and genioglossus muscles, with the periosteum, were then detached posteriorly; mucous membrane incised anteroposteriorly; the necessary teeth extracted; the jaw sawn through at the second molar on the right, and at the last molar tooth on the left side. The mucous membrane was brought together by running suture, thus closing the wound within the mouth. The detached mylohoid muscles were brought forward to the chin wound and sutured. Impressions were made by a dentist of the teeth remaining in the stumps on either side of the jaw—two on the right and one on the left. From the impressions he made gold crowns, which were snugly fitted over the teeth; soldered to these crowns were two heavy strands of platinum wire bent to the shape of the mouth. Before application, this prosthetic measured from crown to crown 1 cm. more than the space between the teeth; that is to say, a line drawn from the molar on the right, across the tongue to the molar on the left, was about 1 cm. shorter than the prosthetic appliance. This acted as a splint and spring, gave no discomfort to the patient, and prevented any contraction toward the middle line by the stumps. It also prevented falling in of the lower lip and allowed perfect cleansing of the mouth and mucous membrane line. At the end of four weeks the wire frame was encased in a hard rubber plate, which the patient is still wearing. This plate is grooved below in its whole length. An upgrowth of tissue is now taking place within the grooved space, which will give a firmer base for the plate, and later it is the intention to make a new plate, with teeth attached, for cosmetic and serviceable purposes. At present the patient gets along very well with the appliance as it is. He has no difficulty in removing and replacing the plate at will, so that it can be thoroughly cleansed.

41. **Endothelioma and Perithelioma of Bone.**—Howard and Crile gives a short résumé of previously reported cases, and also report four new cases, one a primary perithelioma of the left humerus, ending in spontaneous fracture, with metastasis on the tip of the nose, necessitating amputation of the humerus and tip of the nose. Death ensued on the third day. In the second case the tumor was situated in the left humerus, with metastases in the left temporal bone, the pleura, lungs and liver. The patient died about 7 months after the first fracture of the humerus. The third case was one of primary endothelioma springing from the lymph spaces and channels of the lumbar vertebræ, clavicle and ribs, with extensive metastases and a complicating chronic cholecystitis, with gallstones and thickening of the gall bladder. The fourth case was a primary lymphendothelioma of the left femur, with metastases in the inguinal lymph glands. The pathology, histogenesis and clinical history of these tumors are discussed in detail.

42. **Malposition of the Appendix.**—A number of patients operated on by Blake for supposed appendicitis were entirely relieved of their symptoms, yet on examination of the appendix no evidences of inflammation were found. In most of the cases, traction was exerted on the cecum through the appendix by a short mesoappendix; in a few cases the cecum seemed to be suspended by the appendix, being adherent behind the colon. Evidences of inflammation of the appendix were either wholly absent or so trivial as hardly to be sufficient to explain the symptoms. Hence, Blake ascribes the symptoms exhibited by these patients to the relation of the appendix and its mesentery to the cecum rather than to an inflammation of the appendix itself, even if the latter condition were found. He suggests that this relation may also explain the appendiceal pain observed in some cases of movable kidney in which appendicectomy gives relief. In enteroptosis a short mesoappendix may readily cause tugging on the appendix and cecum. Blake also intimates that the constant tug on the appendix and cecum is undoubtedly a cause of true appendicitis.

43. **Cancer of Rectum.**—Hartwell discusses 46 cases, in all of which the patients were operated on for the radical cure of cancer of the rectum, and two cases of inguinal colostomy (1 for cancer and 1 for syphilis of the rectum). Of the 46 patients, 44 were traced to their death or to the present time. A study of these cases shows a probable cure of about 16 per cent., counting freedom of return for three years as a cure. The youngest patient was 23 years old, the oldest 70 years. Seven patients died from the results of the operation, seven died from infection, five patients died from recurrence in less than two years and more than one, four patients died from recurrence in less than three years and more than two. One patient is alive after nine years and eight months; one after four years and six months; two after three years and six months; one after three years and two months; eight patients are alive after less than one year; one after less than two years, and one after less than three years. Hartwell says that an earlier diagnosis and a complete eradication of the growth, done after the following method, promises the most satisfactory results both as regards permanency of cure and functional integrity. An inguinal colostomy is first performed by drawing the sigmoid through an intermuscular incision just external to the left rectus muscle and dividing it between two ligatures. The point of division should be as low in the bowel as possible, thus leaving a large sigmoid pouch

as a reservoir above the new anus. The distal end is closed and dropped into the pelvic cavity, or, if indicated, may be fastened in the lower angle of the wound for the purpose of through-and-through irrigation. In this case, the lower segment must be left sufficiently long not to interfere with the radical incision to be done later. An incision is then made in the linea alba at the same level as the intermuscular incision, or, better, slightly above it and the anterior sheath of the rectus between the two incisions is raised up from the muscle. The proximal end of the gut, with its mesentery, is then drawn under this strong sheath over the rectus muscle and fastened into the skin and fascia wound in the middle line. This opening must not be too small, because it shows a tendency to contract and to form a stricture. The gut is tacked to the peritoneum where it emerges from the peritoneal cavity, and the skin and fascia wound is here closed. A protective dressing can be so applied as to insure almost complete primary union. It is well to insert a small catheter into the proximal gut for a distance of six or eight inches to facilitate the passage of gas during the first days following operation. Three weeks later the radical amputation is done. The patient is put in the exaggerated knee-chest position, which controls to a remarkable degree the venous oozing, and an incision is made from the third sacral vertebra downward to and around the anus. The anus is then tied with a purse-string suture, and the eradication of the growth and all the glands begun. The coccyx and one or two sacral vertebræ are resected, and the presacral tissues as high up as the second vertebra are pushed away from the bone, saving only the sacral nerves. This includes all the lymphatic glands and vessels which are apt to be infected. Ligation of the superior hemorrhoidal artery is next done, and then the gut is free posteriorly. It is now freed laterally and the peritoneum is opened when reached. This permits the drawing down of the rectum even up to the blind end, or, if the end was fastened in the colostomy wound, well up toward that point. In the former case, the whole lower segment will be removed; in the latter the gut is divided between two purse-string sutures, with the actual cautery and the upper end closed. This technic obviates the leaving of a piece of bowel closed at both ends, a procedure which has been shown to be dangerous. Beginning at the upper division, the gut to be removed is separated from its anterior and remaining lateral attachment from above downward, and finally removed in one piece, with all lymphatics and glands attached to it. The peritoneum is sutured, the closed end of the gut, if present, being fastened in the opening, the wound closed, and a small drain put in it. This method can be carried out with no fecal contamination to the wound, and the starting above and working downward has the advantage of avoiding cutting through the infected lymphatic tissues. This advantage is analogous to the one of beginning the removal of breast cancer at the most distal lymphatic glands and working toward the growth in the mammary gland. The detailed histories of the cases are given and the percentage statistics are tabulated.

53 Case of Traumatic Dementia. J. Grinker, Chicago.
54 *Experience with the Serum Treatment in Exophthalmic Goiter. S. Kuh, Chicago.

51. *Talma's Operation.*—Hessert operated on a patient aged 42, who had been a heavy drinker for years, for atrophic cirrhosis of the liver, according to the method outlined by Talma, with the exception, however, that no scarifying was done. The omentum was pulled out and the wound sutured in layers. Some of the stitches held the omentum in place, the latter being spread out between the fascia and the skin so as to favor the establishment of collateral anastomosis. The patient died three months after the omentopexy. The observations made on this case and a review of the literature led Hessert to the following conclusions: 1. The Talma operation does not cure cirrhosis of the liver in advanced stages, but in about 40 per cent. of selected cases may ameliorate some of the symptoms, viz., ascites and hemorrhage. 2. Cases in which the liver was enlarged gave a mortality and a higher percentage of improvement than cases of atrophic liver. 3. Biliary cirrhosis associated with enlarged liver, jaundice, fever, and some ascites is best treated by cholecystostomy and drainage of the bile tracts. 4. Many of the cases which were generally improved by the operation differed in no way from some of those not improved, thus giving no guide for future selection of suitable cases. 5. Suture of the omentum between the layers of the abdominal wall gives a lower mortality and a higher percentage of improvement than merely suture to the parietes. 6. Splenopexy may supplant omentopexy. 7. Cases for operation should be selected carefully with regard to the indications and contraindications. Do not operate in advanced cases as a last resort. 8. Drainage increases the danger of septic peritonitis. 9. The operation is not indicated for ascites due to other causes than cirrhosis, and is contraindicated in the presence of renal or cardiac disease and when evidence does not exist that sufficient functional liver substance remains to maintain life.

54. Serum Treatment of Exophthalmic Goiter.—An experience with 11 cases of exophthalmic goiter receiving the serum treatment demonstrated that while serum is not a specific it is an excellent palliative. The change in the subjective condition of the patient is very striking. Within a few days after taking the first dose of the serum, every one of Kuh's patients felt much better; they were less nervous; the appetite was improved; the patient gained in weight, and the pulse was influenced more than by any other remedy employed in the treatment of the tachycardia of exophthalmic goiter. Kuh does not consider it very probable that the results from the serum can be permanent, but believes that in all likelihood these patients will have to continue taking the serum, or the treatment will have to be repeated from time to time if permanent results are looked for. In one of the cases reported the patient did not receive any serum for two and one-half years and remained in good condition all that time.

Annals of Gynecology and Pediatry, Boston.

55 *Curative Operation for Procidentia Uteri. E. H. Tweedy, Dublin.

55. Curative Operation for Procidentia Uteri.—The first step in Tweedy's operation consists in the removal of a large oval flap of mucous membrane from the anterior vaginal wall, combined with a transverse incision across the cervix, just below the bladder; the latter organ is separated from the cervix and the abdomen opened between it and the uterus. Access to Douglas' cul-de-sac is obtained by a transverse incision made in the usual manner, behind the cervix. These transverse incisions are connected at their extremities by lateral incisions as in the operation for vaginal hysterectomy. An assistant now pulls the cervix forcibly to the left side, while the forefinger passed in front of and the thumb passed behind the broad ligament are made firmly to grasp the base of this structure. The mucous membrane of the lateral fornix is now completely detached from the base of the broad ligament by means of a scissors curved on the flat; during this step the fingers protect the uterine artery and the ureter from injury. A similar procedure is adopted on the opposite side. The bases of the broad ligaments with their ruptured fibrous bands are now brought into clear view; these robust fibrous bands, known as the *ligamenta transversali colli* of Mackenrodt, are composed of dense connective tissue firmly united to the supravaginal portion of the cervix, contain unstriped muscle fiber, and constitute by far the most important elements in keeping the uterus from prolapsing. A curved needle carrying a fine silk suture (No. 4) is passed through the base of the broad ligament near its pelvic extremity, and the other broad ligament is treated in a similar manner. When these ligatures are brought together and loosely tied in front of the internal os, the cervix is seen to be raised upward and backward—slung, as it were, between these reunited fibers of Mackenrodt's ligaments. The loose knot is now united so as to enable the cervix again to be brought down and to permit of its easy amputation. When this is accomplished and all hemorrhage controlled, the cervix is again pushed up, and the threads attached to the broad ligaments at either side of it are tied and knotted in front of and on a level with the internal os. The broad ligaments are still further secured in front of the uterus by uniting them to that structure with several fine silk sutures. The fundus of the uterus, with its intervening layer of peritoneum, is next secured to the anterior vaginal wall above the urethra, and the further steps of the anterior colporrhaphy completed. All that now remains is to perform Hegar's colpoperineorrhaphy and to unite the vaginal skin to that of the cervical mucous membrane.

56. **Dermatitis Herpetiformis in Children.**—Bowen reviews a report of 6 cases of bullous dermatitis following vaccination made several years ago, and adds 9 cases occurring in children varying in age from 3 to 10 years. The vaccination preceded the outbreak of the skin affection in but 3, and in 2 of these cases the interval of time between the vaccination and the first outbreak was so long as to render a causative association extremely doubtful. Bowen believes that in a considerable number of cases of dermatitis herpetiformis, as it occurs in children, the element of multiformity is wholly lacking, the disease showing itself by the recurrence of groups of vesicles and bullæ without other lesions. In a majority of cases the subjective symptoms, such as itching, burning, pain and tingling, are either absent or very slightly accentuated, so that this feature can not be considered one of the four cardinal symptoms of the disease in children. In certain cases vaccination may be the exciting cause of the eruption, not in the sense of an infection, but as one of probably many agents which may produce this train of symptoms in some people. Certain regions of the body are especially affected by the eruption, viz., the parts about the nose, mouth and eyes, the backs of the hands and wrists, the backs of the ankles and feet, and the genital region. Unna's "hydroa puerorum" is to be placed by itself, either as a distinct variety of dermatitis herpetiformis or as an independent affection.

as a reservoir above the new anus. The distal end is closed and dropped into the pelvic cavity, or, if indicated, may be fastened in the lower angle of the wound for the purpose of through-and-through irrigation. In this case, the lower segment must be left sufficiently long not to interfere with the radical incision to be done later. An incision is then made in the linea alba at the same level as the intermuscular incision, or, better, slightly above it and the anterior sheath of the rectus between the two incisions is raised up from the muscle. The proximal end of the gut, with its mesentery, is then drawn under this strong sheath over the rectus muscle and fastened into the skin and fascia wound in the middle line. This opening must not be too small, because it shows a tendency to contract and to form a stricture. The gut is tacked to the peritoneum where it emerges from the peritoneal cavity, and the skin and fascia wound is here closed. A protective dressing can be so applied as to insure almost complete primary union. It is well to insert a small catheter into the proximal gut for a distance of six or eight inches to facilitate the passage of gas during the first days following operation. Three weeks later the radical amputation is done. The patient is put in the exaggerated knee-chest position, which controls to a remarkable degree the venous oozing, and an incision is made from the third sacral vertebra downward to and around the anus. The anus is then tied with a purse-string suture, and the eradication of the growth and all the glands begun. The coccyx and one or two sacral vertebræ are resected, and the presacral tissues as high up as the second vertebra are pushed away from the bone, saving only the sacral nerves. This includes all the lymphatic glands and vessels which are apt to be infected. Ligation of the superior hemorrhoidal artery is next done, and then the gut is free posteriorly. It is now freed laterally and the peritoneum is opened when reached. This permits the drawing down of the rectum even up to the blind end, or, if the end was fastened in the colostomy wound, well up toward that point. In the former case, the whole lower segment will be removed; in the latter the gut is divided between two purse-string sutures, with the actual cautery and the upper end closed. This technic obviates the leaving of a piece of bowel closed at both ends, a procedure which has been shown to be dangerous. Beginning at the upper division, the gut to be removed is separated from its anterior and remaining lateral attachment from above downward, and finally removed in one piece, with all lymphatics and glands attached to it. The peritoneum is sutured, the closed end of the gut, if present, being fastened in the opening, the wound closed, and a small drain put in it. This method can be carried out with no fecal contamination to the wound, and the starting above and working downward has the advantage of avoiding cutting through the infected lymphatic tissues. This advantage is analogous to the one of beginning the removal of breast cancer at the most distal lymphatic glands and working toward the growth in the mammary gland. The detailed histories of the cases are given and the percentage statistics are tabulated.

5. **Regeneration of Nerves.**—In this article Kilvington reports the results of experiments on dogs. From these he concludes that both clinical and theoretical considerations point to nerve splitting being preferable to suturing two distal nerves directly to the central end of one of them. He suggests that nerve splitting be made use of in suitable cases of anterior poliomyelitis.

8. **Method of Guarding the Perineum in Labor.**—Caie says that in the hands of an expert obstetrician rupture of the perineum should be a very rare accident. He states that the various methods of safeguarding the perineum now in use are weak in the following points: (a) In attempting to pull forward the vertex by passing the left hand between the thighs of the mother and employing traction on the scalp. (b) In "supporting the perineum" in the direct method by pressure thereon of the concavity between the thumb and forefinger of the right hand. (c) In endeavoring to push the fetal head forward by the indirect method either by inserting two fingers in the rectum or by pressure on the anus. (d) In the delivery of the shoulders. The following is the method which he has employed successfully:

> When the fetal head is moderately distending the perineum, the latter and the parts adjacent are thoroughly dried with a hot sterilized towel; all moisture must be wiped off. At the moment when the tension on the perineum is approaching its maximum—this can be determined easily with a little experience—the left hand of the accoucheur is employed in pressing slightly on the vertex to prevent any premature or sudden expulsion of the head; there is no necessity for passing the arm between the thighs of the mother. The right hand then grasps the perineum in the manner alluded to in (b), but with this important difference: that between it and the perineum is interposed a hot sterilized towel, in such a way that the edge of the concavity between the thumb and the index finger, the edge of the towel, and the lip of the perineum are just in line with each other, a double fold of the towel to fit into the apex of the concavity having previously been made, to supply the deficiency alluded to at that point. Firm pressure is then exerted at every pain, through the bitemporal diameter of the fetal head, if there appear to be any undue stretching or tendency to laceration. No attempt is made to push the head forward until the occiput ceases to engage behind the pubic arch. By these maneuvers three purposes are served:
>
> 1. By firm pressure through the bitemporal diameter premature extension of the head is prevented, without retarding its progress.
> 2. By means of the drying of the parts and the hot towel a much firmer grip, and consequently much greater support, of the perineum can be obtained than could possibly be produced by the bare hand on a surface which is usually very slippery.
> 3. Uniform pressure is obtained on all parts of the perineum, and the part where there is most stretching receives its due measure of support.

The author calls attention to the danger of laceration from the shoulders and says that if after the head is born gentle traction is made backward the next pain will generally cause the anterior shoulder to free itself from its position behind the pubic arch, while the perineum lies over the posterior shoulder and is subjected to only a moderate degree of tension. If the outlet is small, the anterior arm can usually be extracted with little difficulty after the shoulder, thus substituting a much smaller diameter of the child. If the posterior shoulder be allowed to be born first, the anterior shoulder remains firmly fixed behind the pubic arch, while the posterior shoulder presses against the perineum and again dilates it to its utmost limit.

11. **Angina Pectoris and Allied Conditions.**—Oliver reviews at some length the varieties of angina pectoris, the symptomatology and the pathology. In regard to treatment he says that for patients with pseudoangina much can be done. In all cases of angina, whether true or false, attention should be paid to the condition of the stomach and bowels. Dyspeptic troubles must be rectified and remedies given to check decomposition of food to prevent flatulence and to relieve constipation. Tobacco smoking and the use of alcohol must be entirely prohibited in some people and reduced to a minimum in others. In true angina the patient is living on the brink of a precipice and all worry and anxiety should be avoided. Oliver believes that amyl nitrite is the most useful drug in this condition and that inhalation of a few drops in many cases will cut short an attack. When there are signs of a failing heart behind the peripheral arterial constriction, he thinks it is often desirable to combine digitalis or nux vomica with, for example, ethyl nitrite. The other nitrites, such as nitroglycerin (liquor trinitrini) he thinks are equally useful. In certain individuals with angina pectoris in whom the arteries are so diseased that they do not respond equally over the body to the stimulus of the amyl nitrite, this preparation and its congeners do harm. The arterial tension is already low, and as a consequence some unpleasant effects are produced. In some cases of true angina, morphin or other opium preparations are the only drugs which give relief. In many cases, even when there is no syphilitic taint, iodid of potassium will lengthen the interval between the attacks.

15. **Germ Centers of Lymphatic Glands.**—Cleland calls attention to the resemblance between the "germ centers" of lymphatic glands and secondary carcinomatous deposits. He states that there is no doubt that the former have often been mistaken for the latter, even by competent men, and that cases in which sections from the primary lesion have left the question of malignancy unsettled have been finally classified as such on the finding these apparently secondary deposits in the adjacent lymphatic glands. He states that the cells of which these so-called germ centers consist are larger than the surrounding lymphocytes and have more protoplasm and a larger vesicular nucleus. The whole area stains, too, to a much lighter degree than the parts around. Mitotic figures are nearly always numerous and at the edge of the area the cells rapidly, but by distinct gradations, become converted into lymphocytes, so that no hard and fast line of demarcation limits the area. The areas are usually small and indistinctly circumscribed and in such conditions are not likely to be mistaken for a cancerous growth. In certain circumstances, however, associated with chronic irritation, they assume a most striking appearance. This is associated with increase of size and great increase of mitotic activity in the areas and suggests the idea that it is a form of compensatory hypertrophy. These hypertrophied germ centers form very sharply-defined spherical or oval areas, taking a much lighter stain than the parts around and about as deep as that of an epithelial deposit from the breast. The cells composing them are of nearly uniform size and a little smaller and much more regular than those of cancer; they are closely packed together with very little stroma detectable be-

tween them, though an occasional capillary vessel may be noticed; the nucleus resembles closely that of an epithelial cell; and mitoses are often more numerous or as numerous as in the cancerous growth. All these characters show how hard it may be to distinguish the one from the other. The most important difference between the two is, however, found in the boundary zone of each. The somewhat larger and more irregular cells of the carcinoma are separated sharply and distinctly and often by a thin zone of fibrous stroma from the surrounding lymphocytes and each individual cell at the periphery can be relegated at once and satisfactorily into one or other class of these two. In the outer zones of the germ centers, both germ center cells and lymphocytes tend to be arranged in concentric rings formed of a delicate fibrous tissue and all gradations are seen between undoubted germ-center cells, on the one hand, and undoubted lymphocytes on the other. Under a low power of magnification the germ center often seems sharply delimited from the surrounding parts and the cancerous deposit is less distinctly outlined; with higher magnifying powers this appearance is reversed and the germ center is found, on careful observation, to grade into the lymphatic tissue around while the carcinomatous growth is sharply defined. If during an examination of the lymphatic glands in a doubtful case of carcinoma the possible presence of these hypertrophied centers be borne in mind, it is not likely that any mistake will be made; but should an area of cells be encountered which gives rise to any doubt a careful consideration of the various points of difference enumerated above will enable the observer to satisfy himself as to its nature and may relieve also the mind of the surgeon and of his patient of the distressing dread of a recurrence of a disease which is not there.

24. **Pilocarpin in Beriberi.**—Gebhard reports a case in which pilocarpin was used in beriberi with good results. The most interesting point, he states, was the rapidity with which the edema disappeared after the administration of the drug, as well as the marked improvement in the disease itself. In the case reported, the patient was put on a tonic preparatory to being discharged from the hospital and he immediately suffered a relapse. He was again given pilocarpin and the symptoms subsided.

36. **Threatening Epistaxis in Arteriosclerosis.**—Escat has had opportunity to make careful rhinoscopic examination in 43 cases of threatening epistaxis in arteriosclerotic subjects. It has revealed that the bleeding came from sclerous degeneration of the artery of the nasal septum. This sphenopalatine artery divides generally into several branches and runs a superficial course in the lower part of the septum. He gives illustrations of the points where the hemorrhage usually occurs and also where secondary hemorrhage may be expected. When the hemorrhage does not yield to the ordinary measures, he advises the application of cotton saturated with hydrogen dioxid. This is left for twenty-four hours or longer in severe cases. When removed the points can be thermocauterized or chromic acid may be applied and the nose tamponed. When the tampon is finally removed the patient must be supervised. He should carry cotton constantly with him in case of a recurrence, and should refrain from blowing his nose. Penghawar is particularly useful for a provisional tampon. Adrenalin should be avoided in arteriosclerosis. If it is impossible to discover the focus, the entire wall of the septum should be cauterized and the passage tamponed with penghawar or cotton. Posterior tamponing, he thinks, should be completely rejected.

37. *Leukemia in Animals.*—Weil has observed various forms of leukemia in 5 dogs and in a horse in the last five years, all old animals. Nocard reported 9 horses, 5 cows, 22 dogs and 1 cat affected with leukemia. The picture was about the same as in man, with the exception of 2 out of Weil's 5 dogs. The symptoms and blood findings in these differed materially from those known in man. Attempts to transmit the leukemia from one animal to another have always proved failures. One of the dogs was treated with the *x*-rays, and the results were similar to those observed in the clinic. The leucocytes dropped from 163,000 to 56,000; the polynuclears fell from 95 to 80 per cent., while the macrophages increased from 1 to 14 per cent. Examination of sections of tumors from the living animal showed zones of degeneration in the peripheral regions which had been exposed to the action of the rays, with accumulation of macrophages. These findings suggest that the curative action of the rays is due chiefly to leucolysis and macrophagia.

39. **Alcohol and Strychnin, Alcohol and Venom.**—Valentino has been continuing his experimental research which has demonstrated that alcohol owes its action on the brain to its dehydrating power. It is taken up by the brain in larger amounts than by other tissues, and the dehydration is more intense in the brain on this account, and is the cause of the alcoholic coma. His experiments with strychnin and with snake poison have shown that the dehydrated brain does not take up these poisons as readily as the normal brain. Animals under the influence of the dehydration consequent on injection of large doses of alcohol were able to bear otherwise fatal doses of strychnin or snake poison without injury. The alcohol dehydrating the nerve substance causes an influx of serous fluids into and through the cells, and this washes away the poison seeking to fasten on the cells. These experiments confirm the traditional benefit of large doses of alcohol in snake poisoning, and show that the stupor of drunkenness is due to dehydration of the nerve centers by the alcohol.

41. **Ion Theory in Biology.**—The ultramicroscope has shown that colloids are merely particles in suspension, too small to be seen by an ordinary microscope. Recent researches have demonstrated that precipitation is dependent on the number and valency of the ions in the liquid as well as whether these ions are electrically negative or positive. Des Bancels has lately succeeded in activating the pure pancreatic juice without kinase. Pure pancreatic juice does not digest albumin.

He conceived the idea that it might be possible to make it digest albumin by precipitating the pancreatic juice on the albumin according to the principles of colloid precipitation. He used for the purpose salts of a bivalent base, but still there was no tendency to digest the albumin. He finally succeeded by sensitizing the albumin with another colloid, toluidin blue. This stains the albumin, but does not digest it, but modifies it in such a way that the pancreatic juice then attacks and digests it. Ambard refers also to Loeb's experiments which showed that certain sea animals die in water containing only monovalent ions, while they thrive in water containing small amounts of bivalent salts or mere traces of trivalent salts. The theory of ions seems to throw light on the biologic phenomena of agglutination, hematolysis and digestion, which scientists are now striving to explain by purely physicochemical laws. The recent international congress on radiology of Belgium was officially entitled "Congrès de Radiologie et Ionisation."

43. **Hemophilia in Women.**—De Bovis reviews the literature on the subject of hemophilia and its transmission through generations. He devotes a chapter to its effect on the genital life, the literature showing that pregnancy is rather favorable than otherwise to hemophiliac women, the blood apparently becoming less persistently fluid. In 150 cases of delivery in hemophiliac women, excessive hemorrhage occurred immediately afterward in 69. In 2 cases the mothers were unable to nurse their children, as it seemed to increase the tendency to hemorrhage. Abortions are noted in the history of some hemophiliacs. It is possible that hemophilia may exist in a rudimentary "fruste" form. In a case under De Bovis' observation a iv-para suffered from uterine hemorrhage during a fifth pregnancy. Artificial evacuation of the uterus was suggested, but the curetting was followed by uncontrollable fatal hemorrhage. The patient was not a hemophiliac in the strict sense of the word, but nothing except the hemophiliac diathesis can explain the uncontrollable hemorrhage in this case. De Lee has also reported a case of fatal hemorrhagic diathesis with premature detachment of the placenta, and yet the uterus had contracted. Ahlfeld and Switalsky have also reported similar cases, all distinguished by postpartum hemorrhage occurring in a woman whose menses were always copious, with a history of abortions or of hemorrhagic accidents in herself or in some relative. In De Bovis' service during 1903 there were 476 deliveries. The women had a record of *menstruation for more than five days* in 153 cases and of less than five days in 323. Postpartum hemorrhage occurred in 13 per cent. of the former and in only 8 per cent. of the latter. The hemophiliac tendency may also manifest itself at puberty and at the menopause, remaining latent at other times. Hemophilia, therefore, is a condition which occurs much more frequently than is generally supposed, and women are affected as often, if not oftener than men, but the tendency does not reveal itself in women except at times of physiologic stress naturally tending to hemorrhage. At other times it may be that menstruation acts as a kind of safety valve. Grosglik and Floderus have collected 43 cases of hemophiliac hematuria, and Kroukovsky has related a case of bleeding from the nipple for two years in a woman of 52 who had nursed ten children. De Bovis thinks that marriage should be forbidden in families of notorious bleeders, both to men and women. He has tried injections of gelatin in one case, but without any result. He ascribes the occasional success of general treatment to the fact that the patients are usually neuropathic. The hemorrhages ceased in Anderson's almost moribund patient when she was told to drink "all the champagne she wanted." Brook reported in 1901 an attempt at "antenatal treatment of hemophilia." He administered alternately to a hemophiliac woman during her pregnancy calcium chlorid, strychnin, iron and arsenic, and the results apparently were a complete success. The main reliance in the presence of hemophiliac bleeding is on very hot injections, swabbing with adrenalin and tamponing. Gelatinized dressings might also be used, as suggested by Sahli, or Henkel's plan of compressing with forceps the uterine arteries at the base of the broad ligaments. Steam cauterization of the uterine cavity might also be tried, and, as a last resort, ablation of the bleeding organ. It is generally noticeable that hemophiliacs tolerate operation on the large arterial trunks better than superficial wounds. He relates a number of instances of this paradoxical fact, and remarks that it justifies hysterectomy in case of threatening menorrhagia or metrorrhagia. In 10 cases of death from puerperal hemorrhage in hemophiliacs, 2 occurred after premature delivery and 3 after abortion. The best plain is to await spontaneous expulsion or natural termination of the pregnancy, ready for any emergency, even for hysterectomy.

44. **Malarial Peritonitis.**—Gillot has had occasion to observe several cases of what was apparently acute peritonitis, suggesting perforation in one instance, but the laparotomy revealed the absolute soundness of the peritoneum and intestines. The blood was not examined in this case, but in another, presenting similar symptoms, examination of the blood revealed the parasite of malaria and recovery was rapid under quinin. He urges the possibility of a malarial origin for the syndrome of acute peritonitis occurring in a man or woman in a malarial country or known to have malarial antecedents, even if no parasites are found in the blood. The quinin will not do much harm, even if the peritonitis is not of a malarial nature. In a woman in the fifth month of pregnancy, the symptoms of peritonitis subsided after subcutaneous injection of .75 gm. of quinin, but in his other cases he injected twice this amount. One patient required three repetitions of this dose in the course of a week before convalescence was finally established, although marked improvement followed each dose.

45. **Congenital Megacolon.**—Perthes describes in detail a case in which he restored a lad of 15 to health after five laparotomies in the course of *three years*. A valve formation in the sigmoid flexure was the principal factor in the trouble. Examination of the cadaver in another case showed a somewhat similar mechanism, as also was discovered in a third case. It is possible for the mechanical obstruction to be a valve formation somewhere in the intestines, generally in the flexure, or it may be the result of multiple windings or folds. Volvulus of the flexure has also been observed. He concludes from the lessons learned from his case and from the autopsy findings that in another case of congenital megacolon, *not due to a stricture*, he would proceed to make a wide artificial anus in the descending colon. He would then empty the flexure and the colon during the next few days by cautious irrigation from the rectum. The shape of the abdomen and of the thorax is altered so much by the relief from the distension that it is wise to wait a few weeks or months

before attempting further interference. During this period the existence of the valve in the flexure is verified, and it is removed by a laparotomy after the flexure and colon have been rinsed clean from the new anus. Colopexy or resection of the part of the flexure, with or without invagination, should then be done to meet the indications. If further experience confirms what he thinks is the comparative frequency of valve formation in the flexure as the cause of Hirschsprung's disease, then operative treatment offers promise of fine results.

46 to 49. **Functional Diagnosis of Urinary Apparatus and Surgery.**—The main points in these various communications have been summarized in previous articles by the writers and abstracts published in these columns.

51. **Spinal Anesthesia.**—Bier is proverbially cautious, but he now affirms that although spinal anesthesia is yet far from being perfected, it is already sufficiently advanced for general adoption, especially in cases in which total anesthesia is considered dangerous. It is not entirely free from danger; no intoxication of any kind is absolutely harmless, and spinal as well as general anesthesia is an intoxication. He calls attention to the remarkable way in which the organism tolerates under anesthesia much more severe injuries than without it. Unilateral pneumothorax, for instance, in case of resection of the thoracic wall, or removal of a cyst in the lung, scarcely affects the pulse and respiration in the anesthetized subject. Experiments on dogs showed that they were able to survive being shot at several times until they succumbed to the effects of the hemorrhage; in unanesthetized animals the first shot generally kills, more from psychic shock than from the wound inflicted. Spinal anesthesia reduces the sensibility to shock the same as general anesthesia in these circumstances. Spinal anesthesia, he proclaims, is especially indicated for elderly and debilitated patients. They bear it well and are able to eat at once after the operation. Its superiority in these cases is particularly manifest in comparison of the condition after spinal and general anesthesia for removal of carcinoma of the rectum. The "spinal" patients appear as if they had passed through merely a minor operation, while the "generals" are sick and miserable for days. He is convinced that spinal anesthesia will materially reduce the mortality in these cases. It is a great advance in military and in veterinary surgery, and will undoubtedly aid in physiologic experiments. Improved technic has reduced the dangers to the vanishing point. During his last 300 cases the spinal anesthesia failed in only 4 per cent., and excluding the cases in which the technic was at fault, the failures were in only 2.33 per cent. The moral effect of being a witness to the operation does not seem to detract from its use, as patients who have submitted to both the spinal and general anesthesia almost invariably express their preference for the former, especially the male patients. The addition of a suprarenal preparation to the cocain or stovaine he regards as the most important progress in the technic. He has not had a serious mishap in his 305 cases of spinal anesthesia with this technic.

52. **Suture of Wounds of the Lung.**—Garré has reviewed 700 cases of injuries of the lungs recorded in recent years. He found that 40 per cent. of the 700 cases terminated fatally under conservative treatment. More than half of the 37 cases of rupture of the lung terminated fatally, 38 per cent. of the 100 stab wounds, and 30 per cent. of the 535 bullet wounds. He points to these figures as justifying surgical intervention, and describes a case in which he sutured a ruptured lung for nearly 7 cm., and beheld the previously collapsed lung in the almost moribund patient, a lad of 11, reassume its functions at once. He summarizes the eight published cases of stab or bullet wounds on record treated by suture. Six of the patients recovered. In conclusion he outlines the technic, urging a broad incision, and suture of the lung tissue with fine silk, not drawing the thread very tight.

58. **Injuries from Japanese Firearms.**—Seldowitsch graphically describes his surgical experiences at Tieling after the battle of Liao-yang. His observation has convinced him that firearm wounds of skull and brain—to which his article is principally devoted—require operative intervention almost without exception. The prognosis is bad, but more favorable on the whole, than firearm wounds of the chest. Wounds of the abdomen proved most serious of all.

61. **New Method of Sterilizing the Surgeon's Knives.**—Grosse was experimenting with the sterilization of catheters when he made the discovery that an infected catheter enclosed in a glass cylinder, tightly corked at both ends, became entirely sterile after ten minutes of steam disinfection. The steam does not reach the catheter, and yet it is sterilized. He explains this by assuming that the minute amount of moisture contained in the ordinary air in the cylinder is sufficient to ensure the sterilization of the catheter at the temperature of the steam outside. He at once applied this discovery to the sterilization of knives and is enthusiastic over the fine results attained. The knives come out perfectly dry, unspecked and sharp. He uses an ordinary test tube for the knives, corked tightly, the cork held in place by a small chain and coil of wire around the test tube. The knives rest in a horizontal wire frame inside the glass tube to avoid contact with each other or with the walls. He adds a number of tests made with knives thus disinfected, showing the perfect sterilization thus realized in steam at a temperature of from 98 to 100 C. (boiling point). Hours would be required to accomplish the same result with dry heat.

72 Present Status of Spinal Anesthesia.—Die Lumbalanästhesie. Hildebrandt.

64. **Lumbar Anesthesia with Stovaine.**—Tilman reports extremely satisfactory experiences with spinal anesthesia since the introduction of stovaine. Bier supplements its action with adrenalin, but Tilmann has not found it necessary in his 42 cases. He gives his patients a glass of wine and something to eat immediately after the operation. Few mishaps are credited to stovaine as yet. One reported by Sonnenberg was in the case of a pyemic woman with suppuration in the abdomen who succumbed to suppurative meningitis ten days after a lumbar injection. Chaput has reported a death after lumbar injection of .01 gm. stovaine by a non-surgeon, and he has also witnessed a case of transient collapse. Tilmann has broadened the scope of lumbar anesthesia by utilizing it for the relief of sciatica. His first patient of this kind was a young man of 22, a sufferer from rebellious sciatica. He required an operation for hydrocele, and under stovaine lumbar anesthesia the sciatic pains vanished and they did not recur after the return of sensation. Tilmann seized this opportunity to stretch the nerve by forcible flexion of the thigh, a method which he regards as extremely beneficial in sciatica, but which he is rarely able to apply on account of the excessive painfulness of the procedure. After the fourth day slight sensation returned in the sciatic, but subsided again by the eighth day, and the patient has since been permanently cured. He has had somewhat similar experience with four other patients with sciatica, and recommends a tentative stovaine injection in all cases of sciatica rebellious to internal treatment (castor oil, potassium iodid, quinin), and in which the painfulness renders it impossible to stretch the nerve. Even if used only as a palliative, instead of morphin, the injection of stovaine in the lumbar sac will have a more durable action than the morphin, as in his experience the anesthesia of the sciatic lasted always for four days.

65. **Bone Marrow and Hypoleucocytosis.**—Gütig's patient was a girl of 18 and the blood findings indicated complete insufficiency on the part of the bone marrow. The autopsy revealed pseudoleukemic proliferation of lymphadenoid tissue in the bone marrow and also miliary tuberculosis, both known to

He conceived the idea that it might be possible to make it digest albumin by precipitating the pancreatic juice on the albumin according to the principles of colloid precipitation. He used for the purpose salts of a bivalent base, but still there was no tendency to digest the albumin. He finally succeeded by sensitizing the albumin with another colloid, toluidin blue. This stains the albumin, but does not digest it, but *modifies it in such a way that the pancreatic juice then attacks* and digests it. Ambard refers also to Loeb's experiments which showed that certain sea animals die in water containing only monovalent ions, while they thrive in water containing small amounts of bivalent salts or mere traces of trivalent salts. The theory of ions seems to throw light on the biologic phenomena of agglutination, hematolysis and digestion, which scientists are now striving to explain by purely physicochemical laws. The recent international congress on radiology of Belgium was officially entitled "Congrés de Radiologie et Ionisation."

43. **Hemophilia in Women.**—De Bovis reviews the literature on the subject of hemophilia and its transmission through generations. He devotes a chapter to its effect on the genital life, the literature showing that pregnancy is rather favorable than otherwise to hemophiliac women, the blood apparently becoming less persistently fluid. In 150 cases of delivery in hemophiliac women, excessive hemorrhage occurred immediately afterward in 69. In 2 cases the mothers were unable to nurse their children, as it seemed to increase the tendency to hemorrhage. Abortions are noted in the history of some hemophiliacs. It is possible that hemophilia may exist in a rudimentary "fruste" form. *In a case under De Bovis' observation a iv-para suffered from uterine hemorrhage during a fifth pregnancy.* Artificial evacuation of the uterus was *suggested*, but the curetting was followed by uncontrollable fatal hemorrhage. The patient was not a hemophiliac in the strict sense of the word, but nothing except the hemophiliac diathesis can explain the uncontrollable hemorrhage in this case. De Lee has also reported a case of fatal hemorrhagic diathesis with premature detachment of the placenta, and yet the uterus had contracted. Ahlfeld and Switalsky have also reported similar cases, all distinguished by postpartum hemorrhage occurring in a woman whose menses were always copious, with a history of abortions or of hemorrhagic accidents in herself or in some relative. In De Bovis' service during 1903 there were 476 deliveries. The women had a record of menstruation for more than five days in 153 cases and of less than five days in 323. Postpartum hemorrhage occurred in 13 per cent. of the former and in only 8 per cent. of the latter. The hemophiliac tendency may also manifest itself at puberty and at the menopause, remaining latent at other times. Hemophilia, therefore, is a condition which occurs much more frequently than is generally supposed, and women are affected as often, if not oftener than men, but the tendency does not reveal itself in women except at times of physiologic stress naturally tending to hemorrhage. At other times it may be that menstruation acts as a kind of safety valve. Grosglik and Floderus have collected 43 cases of hemophiliac hematuria, and Kroukovsky has related a case of bleeding from the nipple for two years in a woman of 52 who had nursed ten children. De Bovis thinks that marriage should be forbidden in families of notorious bleeders, both to men and women. He has tried *injections of gelatin in* one case, but without any result. He ascribes the occasional success of general treatment to the fact that the patients are usually neuropathic. The hemorrhages ceased in Anderson's almost moribund patient when she was told to drink "all the champagne she wanted." Brook reported in 1901 an attempt at "antenatal treatment of hemophilia." He administered alternately to a hemophiliac woman during her pregnancy calcium chlorid, strychnin, iron and arsenic, and the results apparently were a complete success. The main reliance in the presence of hemophiliac bleeding is on very hot injections, swabbing with adrenalin and tamponing. Gelatinized dressings might also be used, as suggested by Sahli, or Henkel's plan of compressing with forceps the uterine arteries at the base of the broad ligaments. Steam cauterization of the uterine cavity might also be tried, and, as a last resort, ablation of the bleeding organ. It is generally noticeable that hemophiliacs tolerate operation on the large arterial trunks better than superficial wounds. He relates a number of instances of this paradoxical fact, and remarks that it justifies hysterectomy in case of threatening menorrhagia or metrorrhagia. In 10 cases of death from puerperal hemorrhage in hemophiliacs, 2 occurred after premature delivery and 3 after abortion. The best *plain is to await spontaneous expulsion* or natural termination of the pregnancy, ready for any emergency, even for hysterectomy.

44. **Malarial Peritonitis.**—Gillot has had occasion to observe several cases of what was apparently acute peritonitis, suggesting perforation in one instance, but the laparotomy revealed the absolute soundness of the peritoneum and intestines. *The blood was not examined in this case, but in another*, presenting similar symptoms, examination of the blood *revealed the parasite of malaria* and recovery was rapid under quinin. He urges the possibility of a malarial origin for the syndrome of *acute peritonitis occurring in a man or woman in a malarial country or known to have malarial antecedents*, even if no parasites are found in the blood. The quinin will not do much harm, even if the peritonitis is not of a malarial nature. In a woman in the fifth month of pregnancy, the symptoms of peritonitis subsided after subcutaneous injection of .75 gm. of quinin, but in his other cases he injected twice this amount. One patient required three repetitions of this dose in the course of a week before convalescence was finally established, although marked improvement followed each dose.

45. **Congenital Megacolon.**—Perthes describes in detail a case in which he restored a lad of 15 to health after five laparotomies in the course of three years. A valve formation in the sigmoid flexure was the principal factor in the trouble. Examination of the cadaver in another case showed a somewhat similar mechanism, as also was discovered in a third case. It is possible for the mechanical obstruction to be a valve formation *somewhere* in the intestines, generally in the flexure, or it may be the result of multiple windings or folds. *Volvulus* of the flexure has also been observed. He concludes from the lessons learned from his case and from the autopsy findings that in another case of congenital megacolon, not due to a stricture, he would proceed to make a wide artificial anus in the descending colon. He would then empty the flexure and the colon during the next few days by cautious irrigation from the rectum. The shape of the abdomen and of the thorax is altered so much by the relief from the distension that it is wise to wait a few weeks or months

before attempting further interference. During this period the existence of the valve in the flexure is verified, and it is removed by a laparotomy after the flexure and colon have been rinsed clean from the new anus. Colopexy or resection of the part of the flexure, with or without invagination, should then be done to meet the indications. If further experience confirms what he thinks is the comparative frequency of valve formation in the flexure as the cause of Hirschsprung's disease, then operative treatment offers promise of fine results.

46 to 49. Functional Diagnosis of Urinary Apparatus and Surgery.—The main points in these various communications have been summarized in previous articles by the writers and abstracts published in these columns.

51. Spinal Anesthesia.—Bier is proverbially cautious, but he now affirms that although spinal anesthesia is yet far from being perfected, it is already sufficiently advanced for general adoption, especially in cases in which total anesthesia is considered dangerous. It is not entirely free from danger; no intoxication of any kind is absolutely harmless, and spinal as well as general anesthesia is an intoxication. He calls attention to the remarkable way in which the organism tolerates under anesthesia much more severe injuries than without it. Unilateral pneumothorax, for instance, in case of resection of the thoracic wall, or removal of a cyst in the lung, scarcely affects the pulse and respiration in the anesthetized subject. Experiments on dogs showed that they were able to survive being shot at several times until they succumbed to the effects of the hemorrhage; in unanesthetized animals the first shot generally kills, more from psychic shock than from the wound inflicted. Spinal anesthesia reduces the sensibility to shock the same as general anesthesia in these circumstances. Spinal anesthesia, he proclaims, is especially indicated for elderly and debilitated patients. They bear it well and are able to eat at once after the operation. Its superiority in these cases is particularly manifest in comparison of the condition after spinal and general anesthesia for removal of carcinoma of the rectum. The "spinal" patients appear as if they had passed through merely a minor operation, while the "generals" are sick and miserable for days. He is convinced that spinal anesthesia will materially reduce the mortality in these cases. It is a great advance in military and in veterinary surgery, and will undoubtedly aid in physiologic experiments. Improved technic has reduced the dangers to the vanishing point. During his last 300 cases the spinal anesthesia failed in only 4 per cent., and excluding the cases in which the technic was at fault, the failures were in only 2.33 per cent. The moral effect of being a witness to the operation does not seem to detract from its use, as patients who have submitted to both the spinal and general anesthesia almost invariably express their preference for the former, especially the male patients. The addition of a suprarenal preparation to the cocain or stovaine he regards as the most important progress in the technic. He has not had a serious mishap in his 305 cases of spinal anesthesia with this technic.

52. Suture of Wounds of the Lung.—Garré has reviewed 700 cases of injuries of the lungs recorded in recent years. He found that 40 per cent. of the 700 cases terminated fatally under conservative treatment. More than half of the 37 cases of rupture of the lung terminated fatally, 38 per cent. of the 100 stab wounds, and 30 per cent. of the 535 bullet wounds. He points to these figures as justifying surgical intervention, and describes a case in which he sutured a ruptured lung for nearly 7 cm., and beheld the previously collapsed lung in the almost moribund patient, a lad of 11, reassume its functions at once. He summarizes the eight published cases of stab or bullet wounds on record treated by suture. Six of the patients recovered. In conclusion he outlines the technic, urging a broad incision, and suture of the lung tissue with fine silk, not drawing the thread very tight.

58. Injuries from Japanese Firearms.—Seldowitsch graphically describes his surgical experiences at Tieling after the battle of Liao-yang. His observation has convinced him that firearm wounds of skull and brain—to which his article is principally devoted—require operative intervention almost without exception. The prognosis is bad, but more favorable on the whole, than firearm wounds of the chest. Wounds of the abdomen proved most serious of all.

61. New Method of Sterilizing the Surgeon's Knives.—Grosse was experimenting with the sterilization of catheters when he made the discovery that an infected catheter enclosed in a glass cylinder, tightly corked at both ends, became entirely sterile after ten minutes of steam disinfection. The steam does not reach the catheter, and yet it is sterilized. He explains this by assuming that the minute amount of moisture contained in the ordinary air in the cylinder is sufficient to ensure the sterilization of the catheter at the temperature of the steam outside. He at once applied this discovery to the sterilization of knives and is enthusiastic over the fine results attained. The knives come out perfectly dry, unspecked and sharp. He uses an ordinary test tube for the knives, corked tightly, the cork held in place by a small chain and coil of wire around the test tube. The knives rest in a horizontal wire frame inside the glass tube to avoid contact with each other or with the walls. He adds a number of tests made with knives thus disinfected, showing the perfect sterilization thus realized in steam at a temperature of from 98 to 100 C. (boiling point). Hours would be required to accomplish the same result with dry heat.

64. Lumbar Anesthesia with Stovaine.—Tilman reports extremely satisfactory experiences with spinal anesthesia since the introduction of stovaine. Bier supplements its action with adrenalin, but Tilmann has not found it necessary in his 42 cases. He gives his patients a glass of wine and something to eat immediately after the operation. Few mishaps are credited to stovaine as yet. One reported by Sonnenberg was in the case of a pyemic woman with suppuration in the abdomen who succumbed to suppurative meningitis ten days after a lumbar injection. Chaput has reported a death after lumbar injection of .01 gm. stovaine by a non-surgeon, and he has also witnessed a case of transient collapse. Tilmann has broadened the scope of lumbar anesthesia by utilizing it for the relief of sciatica. His first patient of this kind was a young man of 22, a sufferer from rebellious sciatica. He required an operation for hydrocele, and under stovaine lumbar anesthesia the sciatic pains vanished and they did not recur after the return of sensation. Tilmann seized this opportunity to stretch the nerve by forcible flexion of the thigh, a method which he regards as extremely beneficial in sciatica, but which he is rarely able to apply on account of the excessive painfulness of the procedure. After the fourth day slight sensation returned in the sciatic, but subsided again by the eighth day, and the patient has since been permanently cured. He has had somewhat similar experience with four other patients with sciatica, and recommends a tentative stovaine injection in all cases of sciatica rebellious to internal treatment (castor oil, potassium iodid, quinin), and in which the painfulness renders it impossible to stretch the nerve. Even if used only as a palliative, instead of morphin, the injection of stovaine in the lumbar sac will have a more durable action than the morphin, as in his experience the anesthesia of the sciatic lasted always for four days.

65. Bone Marrow and Hypoleucocytosis.—Gütig's patient was a girl of 18 and the blood findings indicated complete insufficiency on the part of the bone marrow. The autopsy revealed pseudoleukemic proliferation of lymphadenoid tissue in the bone marrow and also miliary tuberculosis, both known to have an injurious action on the marrow, and thus superposing their effects in the present case.

67. Bacteriologic Examination of Cases of Tuberculosis Without Sputa.—Blume has found it impossible in a number of cases of incipient tuberculosis to obtain enough sputum for examination. He gives such patients an ordinary object-glass, mounted in a frame like a hand mirror, and instructs them to hold the glass opposite their mouth as they cough every morning, for from eight to ten days, and then to send the glass to him, packed loosely in paper. Microscopic examination then follows after the usual double staining.

70. Improved Test for Lactic Acid.—Croner and Cronheim recommend as sensitive and reliable the following modified test: Two grains of potassium iodid are dissolved in 5 c.c. of water or less, and 1 gm. of sublimated, pulverized iodin is added. After all is dissolved, it is filtered through asbestos or glass wool and diluted to 50 c.c. About 5 c.c. of anilin is then added to the fluid, which is set aside in a dark-colored vial. It will keep for several months. The stomach content to be examined is diluted with water, rendered alkaline with 10 per cent. caustic potash, boiled for a few minutes, and then a few c.c. of the reagent are mixed with it. In the presence of lactic acid the odor of isonitril becomes perceptible at once or after renewed boiling, supplanting the odor of the anilin. The test was positive in one experience, even in the presence of only .0025 gm. of lactic acid to 100 c.c. of the diluted solution. Alcohol and acetone give the same reaction, but can readily be removed.

71. High Injections into the Intestines.—Years of experience have confirmed von Aldor's previous announcements in regard to the great benefit to be derived from injections carried high into the bowels. He uses a soft Nélaton sound, like a stomach tube, and guards against its rolling up at the sigmoid flexure by digital examination. The patient lies on the left side. Experiments with tubes coated with bismuth in a mixture of oil, glycerin and gum arabic showed that the tubes actually made their way into the higher parts of the gut, as could be seen by the *x*-rays. He gives two illustrations, one showing the wrong way to introduce the tube and its rolling up in the ampulla, the other showing the right way and the course of the tube as it reached the higher regions. The walls of the intestines can be treated just where desired through the tube, and medicated fluids introduced. When the fluid is injected without a tube, most of it accumulates in the lower bowel and very little, if any, finds its way to the higher regions. High injections of Carlsbad water have proved exceedingly useful in certain cases.

78. Chemical and Histologic Findings in Leukemia After Roentgen Treatment.—The patient was a man of 36, previously healthy, with myeloid leukemia for two or three years before it terminated fatally. Forty Roentgen exposures were made, but did not seem to arrest the progress of the disease after a first, transient improvement. The composition of the blood and the blood findings changed under the exposures, finally presenting the picture accompanying aplasia of the blood-forming organs, and the anatomic findings were those of hypoplasia. It was most pronounced in the bone marrow, but was also unmistakable in the spleen and lymph glands. It was accompanied by pronounced proliferation of the interstitial tissue. Lossen and Morawitz are inclined to regard the hypoplasia as favored and possibly originated by the three weeks of rather intense Roentgen treatment given in this case. Of 7 leukemic patients treated by Roentgen exposures, 3 were materially improved and the others are still under treatment, with the exception of the fatal case mentioned above. In one case of myeloid leukemia the leucocyte formula became normal and the elimination of uric acid also returned to normal proportions. This suggests an increased new formation of leucocytes as probable. In the first case with extreme leucopenia, the amount of uric acid eliminated remained abnormally high throughout.

81. Urine in Febrile Diseases.—Klieneberger and Oxenius made 808 examinations of the urine of 79 men and 63 women suffering from a great variety of febrile affections, leukemia, icterus and diabetes. Their conclusions are to the effect that the urine is liable to be modified by toxic influences, apart from the fever or the general condition. They deny the existence of "febrile albuminuria" in the old sense. The changes in the urine in icterus and in diabetes are more pronounced than in most febrile affections. Sometimes there is a sudden copious evacuation of albumin and tube casts, possibly due to some disturbance in the circulation which may correct itself later.

82. Blood Pressure Measurements.—Geisböck has been making a systematic study of the blood pressure in a large number of diseases to determine the action of certain drugs and food and the effect of muscular exertion on the patients. He found the pressure at the lower limit of normal range or slightly below in tuberculosis, averaging 70 to 90 mm. Complications did not send the blood pressure up, as under other circumstances, and in 11 patients giving a febrile reaction to .5 mg. tuberculin the blood pressure sank from 15 to 40 mm. and remained low for from two to six days. The pressure was also low in pneumonia and typhoid. Caffein or digitalis were given in nine cases, but they did not raise the pressure, possibly due to the injury of the vasomotor nerves in these diseases. The blood pressure rose regularly when an ice bag was applied to the abdomen. This effect might be utilized in severe cases of pneumonia to raise the blood pressure by driving the accumulated blood out of the splanchnic region. The blood pressure rose to 120 mm. in less than twenty-four hours after the onset of acute nephritis resulting from ingestion of corrosive sublimate in one case, and had risen to 135 mm. by the sixth day. As there was no time in this case for hypertrophy of the heart to develop, it demonstrates that the rise was due directly to the kidney affection. The pressure was also high in a group of cases of acute, brief, postinfluenza nephritis. The highest pressure noted was in cases of contracted kidney (up to 250 mm.) In dubious cases, high arterial pressure speaks in favor of a nephritis. Suppurative, toxic and septic cases generally have a low pressure. In cases of heart affections, he found that a lower blood pressure after muscular exertion, such as climbing stairs, is a reliable sign of some affection of the heart musculature. It may serve to differentiate the organic from the merely functional affections of the heart. Arteriosclerosis may be the result of long-continued exaggerated high blood pressure, or the high pressure may be the result of diffuse sclerosis of the arterioles. Digitalis lowered the blood pressure, especially when the edema and serous effusions were subsiding, and other diuretics and purgatives acted on the effusions, but did not seem to affect the blood pressure. Tapping the ascites had a decidedly favorable action in reducing the blood pressure. Chloral did not reduce the pressure to any extent in the two cases of heart disease he reports. In the course of his research he encountered a number of patients with remarkably high blood pressure, large numbers of red corpuscles and very high proportion of hemoglobin. These patients were all over 40. The women were generally corpulent and well-to-do, and the men had for years been conducting large enterprises with much responsibility and mental strain. Abuse of alcohol and tobacco was common, as also hereditary influences. He calls this condition "polycythemia hypertonica," and remarks that signs of arteriosclerosis could not be detected in a number of them, although a connection seemed to be apparent in others. Slight albuminuria was the rule, with few exceptions. Apoplexy occurred in 8 of his 17 cases. In advanced cases of contracted kidney Geisböck found no increase, but rather a decrease in the numbers of red corpuscles, but in incipient cases of contracted kidney and in certain other forms of kidney affections the proportions may be unduly high. This was found in one instance in which a man of 51 was brought to the clinic after a severe attack of apoplexy with a blood pressure of 250 mm., 5,700,000 red corpuscles, hypertrophy of the heart and throbbing arteries. The autopsy findings were those of pronounced but not far advanced contracted kidney, with moderate arteriosclerosis and cerebral hemorrhage. This case seems to indicate some connection between the "polycythemia hypertonica" and the chronic kidney affection.

83. **Treatment of Arteriosclerosis.**—Romberg reiterates the necessity for gentle, persevering measures in arteriosclerosis, avoiding abrupt changes in medicines or diet. The efficacy of small doses of potassium iodid has been long established, and recent researches show that this drug reduces the viscosity of the blood by acting on the corpuscles, making it more fluid without diluting it. He prescribes it five times a day in doses of .1 or .3 gm., to be kept up for two or three years, with suspension one week in each month and one month after every three. Gastric disturbances should be avoided by refraining from all acids in the food and drinks while it is being taken He sometimes orders it with sodium bicarbonate, to be given in milk. He warns directly against its use in cases of uremic edema of the lung occurring under the picture of cardial asthma, and also whenever the arteriosclerosis is complicated with any manifestations of exophthalmic goiter. In other cases the benefit may even include retrogression of organic lesions, although it is impossible to expect retrogression of thrombosis in a vessel in the brain or of fibrous degeneration of the heart muscle or contracted kidney. It is of the greatest importance to reduce to the minimum the demands on the arteries. Sufficient sleep is also to be insured, even with drugs at first.

86. **Etiology of Regular Enlargement of Esophagus.**—Richartz describes a case of spindle-shaped, regular enlargement of the esophagus, and discusses its possible origin. He thinks that the trouble may be the result of congenital or acquired weakness of the musculature of the esophagus, or that it may be of neurogenetic origin, a *primary, autochthonous* spasm of the cardia combining with dilatation from some affection of the vagus to produce the general enlargement.

87. **Feeding and Draining the Intestine Through Laparotomy Wound.**—For five years von Stubenrauch has been supplying nourishment to certain laparotomy patients by injecting a nourishing fluid into the intestine while it is exposed during the laparotomy. He reviews the drawbacks of nutrient enemata and the frequent lack of absorption, and then describes his experience in fifteen cases in which he drew a loop out of the laparotomy wound, choosing one a yard or more from the seat of operation, and while it was outside the abdomen he punctured and evacuated its contents, substituting them with a quart of milk containing the yolks of eggs, salt, sugar and other ingredients. No mishap occurred in any case, and the patients were thus nourished from the start, without taxing the stomach or wasting time on nutrient enema. This injection stimulates peristalsis, which is liable to be more or less inhibited by the operation. He is careful not to stimulate it too much, and for this reason avoids large amounts of sugar, alcohol and salt in the fluid introduced. A very much debilitated patient is prepared by rectal injection of a solution of sugar and salt in small amounts repeated several times during the day, or by subcutaneous saline infusion or subcutaneous injection of olive oil. During the laparotomy, about a quart of the intestine food is introduced, and afterward a pint of saline solution is poured into the abdomen and a quart is injected subcutaneously. Nothing is allowed by the mouth during the first twelve hours, but the mouth is rinsed out occasionally. After twelve hours, tablespoonfuls of cold tea are given and after the second day milk, etc., several times during the day in small amounts. In cases requiring artificial feeding for only a few days, he sutures the loop of the intestine to the abdominal wound so that food can be introduced directly into the intestine as needed, but if the artificial feeding has to be kept up for some time he makes a fistula according to the Witzel, Albert or Maydl technic. This suturing of the intestinal loop to the lips of the wound has proved a life-saving measure in several cases of ileus, allowing gradual evacuation of the gases and fluid intestinal contents, though a metal cannula. He covers the exposed intestine with a disinfecting paste. He describes his technic in detail and cites a number of cases which have established its benefits.

89. **Radioactivity.**—Bergell reports that radioactivated water promotes the action of the pancreatic juice. Bickel has recently announced that radioactivated water is able to stimulate to greater activity fresh gastric juice from the dog, obtained through a Pawlow fistula. Radioactivated mineral water also accelerates the process of digestion more than ordinary water. Bergell has evolved a method of detecting radioactive emanations in mineral water by means of fractioned cooling. He describes his apparatus for the purpose, and suggests that it may be possible to retain the natural emanations in mineral waters by rapid cooling. The emanation he declares to be a gas which condenses at very low temperatures and which can be extracted from solutions of the radium salts.

90. **Stovaine as a Local Anesthetic.**—Schiff has used stovaine in 203 cases with but a single mishap. This was observed in a patient four hours after some teeth had been extracted under stovaine. The nausea, depression and palpitations observed could be ascribed only to the preceding anesthetic. It is possible that the patient may have swallowed some of the solution used about the teeth.

93. **Spirochetes in Syphilis.**—Rille has succeeded in finding the *Spirochæta pallida* in the extragenital lesions of syphilis and also in syphilitic lesions eight or nine years after infection. He gives the particulars of 14 cases, urging that others should mention the age of the syphilis and the clinical manifestations in referring to the finding of spirochetes.

95. **Action of Radium on Infectious Agents and on Infected Tissues.**—Werner writes from Czerny's clinic at Heidelberg to report research which has demonstrated that the radium rays not only kill bacteria, but also deprive them of toxic action. The toxicity is abolished without interfering with the property

have an injurious action on the marrow, and thus superposing their effects in the present case.

67. Bacteriologic Examination of Cases of Tuberculosis Without Sputa.—Blume has found it impossible in a number of cases of incipient tuberculosis to obtain enough sputum for examination. He gives such patients an ordinary object-glass, mounted in a frame like a hand mirror, and instructs them to hold the glass opposite their mouth as they cough every morning, for from eight to ten days, and then to send the glass to him, packed loosely in paper. Microscopic examination then follows after the usual double staining.

70. Improved Test for Lactic Acid.—Croner and Cronheim recommend as sensitive and reliable the following modified test: Two grains of potassium iodid are dissolved in 5 c.c. of water or less, and 1 gm. of sublimated, pulverized iodin is added. After all is dissolved, it is filtered through asbestos or glass wool and diluted to 50 c.c. About 5 c.c. of anilin is then added to the fluid, which is set aside in a dark-colored vial. It will keep for several months. The stomach content to be examined is diluted with water, rendered alkaline with 10 per cent. caustic potash, boiled for a few minutes, and then a few c.c. of the reagent are mixed with it. In the presence of lactic acid the odor of isonitril becomes perceptible at once or after renewed boiling, supplanting the odor of the anilin. The test was positive in one experience, even in the presence of only .0025 gm. of lactic acid to 100 c.c. of the diluted solution. Alcohol and acetone give the same reaction, but can readily be removed.

71. High Injections into the Intestines.—Years of experience have confirmed von Aldor's previous announcements in regard to the great benefit to be derived from injections carried high into the bowels. He uses a soft Nélaton sound, like a stomach tube, and guards against its rolling up at the sigmoid flexure by digital examination. The patient lies on the left side. Experiments with tubes coated with bismuth in a mixture of oil, glycerin and gum arabic showed that the tubes actually made their way into the higher parts of the gut, as could be seen by the *x*-rays. He gives two illustrations, one showing the wrong way to introduce the tube and its rolling up in the ampulla, the other showing the right way and the course of the tube as it reached the higher regions. The walls of the intestines can be treated just where desired through the tube, and medicated fluids introduced. When the fluid is injected without a tube, most of it accumulates in the lower bowel and very little, if any, finds its way to the higher regions. High injections of Carlsbad water have proved exceedingly useful in certain cases.

78. Chemical and Histologic Findings in Leukemia After Roentgen Treatment.—The patient was a man of 36, previously healthy, with myeloid leukemia for two or three years before it terminated fatally. Forty Roentgen exposures were made, but did not seem to arrest the progress of the disease after a first, transient improvement. The composition of the blood and the blood findings changed under the exposures, finally presenting the picture accompanying aplasia of the blood-forming organs, and the anatomic findings were those of hypoplasia. It was most pronounced in the bone marrow, but was also unmistakable in the spleen and lymph glands. It was accompanied by pronounced proliferation of the interstitial tissue. Lossen and Morawitz are inclined to regard the hypoplasia as favored and possibly originated by the three weeks of rather intense Roentgen treatment given in this case. Of 7 leukemic patients treated by Roentgen exposures, 3 were materially improved and the others are still under treatment, with the exception of the fatal case mentioned above. In one case of myeloid leukemia the leucocyte formula became normal and the elimination of uric acid also returned to normal proportions. This suggests an increased new formation of leucocytes as probable. In the first case with extreme leucopenia, the amount of uric acid eliminated remained abnormally high throughout.

81. Urine in Febrile Diseases.—Klieneberger and Oxenius made 808 examinations of the urine of 79 men and 63 women suffering from a great variety of febrile affections, leukemia, icterus and diabetes. Their conclusions are to the effect that the urine is liable to be modified by toxic influences, apart from the fever or the general condition. They deny the existence of "febrile albuminuria" in the old sense. The changes in the urine in icterus and in diabetes are more pronounced than in most febrile affections. Sometimes there is a sudden copious evacuation of albumin and tube casts, possibly due to some disturbance in the circulation which may correct itself later.

82. Blood Pressure Measurements.—Geisböck has been making a systematic study of the blood pressure in a large number of diseases to determine the action of certain drugs and food and the effect of muscular exertion on the patients. He found the pressure at the lower limit of normal range or slightly below in tuberculosis, averaging 70 to 90 mm. Complications did not send the blood pressure up, as under other circumstances, and in 11 patients giving a febrile reaction to .5 mg. tuberculin the blood pressure sank from 15 to 40 mm. and remained low for from two to six days. The pressure was also low in pneumonia and typhoid. Caffein or digitalis were given in nine cases, but they did not raise the pressure, possibly due to the injury of the vasomotor nerves in these diseases. The blood pressure rose regularly when an ice bag was applied to the abdomen. This effect might be utilized in severe cases of pneumonia to raise the blood pressure by driving the accumulated blood out of the splanchnic region. The blood pressure rose to 120 mm. in less than twenty-four hours after the onset of acute nephritis resulting from ingestion of corrosive sublimate in one case, and had risen to 135 mm. by the sixth day. As there was no time in this case for hypertrophy of the heart to develop, it demonstrates that the rise was due directly to the kidney affection. The pressure was also high in a group of cases of acute, brief, postinfluenza nephritis. The highest pressure noted was in cases of contracted kidney (up to 250 mm.) In dubious cases, high arterial pressure speaks in favor of a nephritis. Suppurative, toxic and septic cases generally have a low pressure. In cases of heart affections, he found that a lower blood pressure after muscular exertion, such as climbing stairs, is a reliable sign of some affection of the heart musculature. It may serve to differentiate the organic from the merely functional affections of the heart. Arteriosclerosis may be the result of long-continued exaggerated high blood pressure, or the high pressure may be the result of diffuse sclerosis of the arterioles. Digitalis lowered the blood pressure, especially when the edema and serous effusions were subsiding, and other diuretics and purgatives acted on the effusions, but did not seem to affect the blood pressure. Tapping the ascites had a decidedly favorable action in reducing the blood pressure. Chloral did not reduce the pressure to any extent in the two cases of heart disease he reports. In the course of his research he encountered a number of patients with remarkably high blood pressure, large numbers of red corpuscles and very high proportion of hemoglobin. These patients were all over 40. The women were generally corpulent and well-to-do, and the men had for years been conducting large enterprises with much responsibility and mental strain. Abuse of alcohol and tobacco was common, as also hereditary influences. He calls this condition "polycythemia hypertonica," and remarks that signs of arteriosclerosis could not be detected in a number of them, although a connection seemed to be apparent in others. Slight albuminuria was the rule, with few exceptions. Apoplexy occurred in 8 of his 17 cases. In advanced cases of contracted kidney Geisböck found no increase, but rather a decrease in the numbers of red corpuscles, but in incipient cases of contracted kidney and in certain other forms of kidney affections the proportions may be unduly high. This was found in one instance in which a man of 51 was brought to the clinic after a severe attack of apoplexy with a blood pressure of 250 mm., 5,700,000 red corpuscles, hypertrophy of the heart and throbbing arteries. The autopsy findings were those of pronounced but not far advanced contracted kidney, with moderate arteriosclerosis and cerebral hemorrhage. This case seems to indicate some connection between the "polycythemia hypertonica" and the chronic kidney affection.

83. **Treatment of Arteriosclerosis.**—Romberg reiterates the necessity for gentle, persevering measures in arteriosclerosis, avoiding abrupt changes in medicines or diet. The efficacy of small doses of potassium iodid has been long established, and recent researches show that this drug reduces the viscosity of the blood by acting on the corpuscles, making it more fluid without diluting it. He prescribes it five times a day in doses of .1 or .3 gm., to be kept up for two or three years, with suspension one week in each month and one month after every three. Gastric disturbances should be avoided by refraining from all acids in the food and drinks while it is being taken He sometimes orders it with sodium bicarbonate, to be given in milk. He warns directly against its use in cases of uremic edema of the lung occurring under the picture of cardial asthma, and also whenever the arteriosclerosis is complicated with any manifestations of exophthalmic goiter. In other cases the benefit may even include retrogression of organic lesions, although it is impossible to expect retrogression of thrombosis in a vessel in the brain or of fibrous degeneration of the heart muscle or contracted kidney. It is of the greatest importance to reduce to the minimum the demands on the arteries. Sufficient sleep is also to be insured, even with drugs at first.

86. **Etiology of Regular Enlargement of Esophagus.**—Richartz describes a case of spindle-shaped, regular enlargement of the esophagus, and discusses its possible origin. He thinks that the trouble may be the result of congenital or acquired weakness of the musculature of the esophagus, or that it may be of neurogenetic origin, a primary, autochthonous spasm of the cardia combining with dilatation from some affection of the vagus to produce the general enlargement.

87. **Feeding and Draining the Intestine Through Laparotomy Wound.**—For five years von Stubenrauch has been supplying nourishment to certain laparotomy patients by injecting a nourishing fluid into the intestine while it is exposed during the laparotomy. He reviews the drawbacks of nutrient enemata and the frequent lack of absorption, and then describes his experience in fifteen cases in which he drew a loop out of the laparotomy wound, choosing one a yard or more from the seat of operation, and while it was outside the abdomen he punctured and evacuated its contents, substituting them with a quart of milk containing the yolks of eggs, salt, sugar and other ingredients. No mishap occurred in any case, and the patients were thus nourished from the start, without taxing the stomach or wasting time on nutrient enema. This injection stimulates peristalsis, which is liable to be more or less inhibited by the operation. He is careful not to stimulate it too much, and for this reason avoids large amounts of sugar, alcohol and salt in the fluid introduced. A very much debilitated patient is prepared by rectal injection of a solution of sugar and salt in small amounts repeated several times during the day, or by subcutaneous saline infusion or subcutaneous injection of olive oil. During the laparotomy, about a quart of the intestine food is introduced, and afterward a pint of saline solution is poured into the abdomen and a quart is injected subcutaneously. Nothing is allowed by the mouth during the first twelve hours, but the mouth is rinsed out occasionally. After twelve hours, tablespoonfuls of cold tea are given and after the second day milk, etc., several times during the day in small amounts. In cases requiring artificial feeding for only a few days, he sutures the loop of the intestine to the abdominal wound so that food can be introduced directly into the intestine as needed, but if the artificial feeding has to be kept up for some time he makes a fistula according to the Witzel, Albert or Maydl technic. This suturing of the intestinal loop to the lips of the wound has proved a life-saving measure in several cases of ileus, allowing gradual evacuation of the gases and fluid intestinal contents, though a metal cannula. He covers the exposed intestine with a disinfecting paste. He describes his technic in detail and cites a number of cases which have established its benefits.

89. **Radioactivity.**—Bergell reports that radioactivated water promotes the action of the pancreatic juice. Bickel has recently announced that radioactivated water is able to stimulate to greater activity fresh gastric juice from the dog, obtained through a Pawlow fistula. Radioactivated mineral water also accelerates the process of digestion more than ordinary water. Bergell has evolved a method of detecting radioactive emanations in mineral water by means of fractioned cooling. He describes his apparatus for the purpose, and suggests that it may be possible to retain the natural emanations in mineral waters by rapid cooling. The emanation he declares to be a gas which condenses at very low temperatures and which can be extracted from solutions of the radium salts.

90. **Stovaine as a Local Anesthetic.**—Schiff has used stovaine in 203 cases with but a single mishap. This was observed in a patient four hours after some teeth had been extracted under stovaine. The nausea, depression and palpitations observed could be ascribed only to the preceding anesthetic. It is possible that the patient may have swallowed some of the solution used about the teeth.

93. **Spirochetes in Syphilis.**—Rille has succeeded in finding the *Spirochæta pallida* in the extragenital lesions of syphilis and also in syphilitic lesions eight or nine years after infection. He gives the particulars of 14 cases, urging that others should mention the age of the syphilis and the clinical manifestations in referring to the finding of spirochetes.

95. **Action of Radium on Infectious Agents and on Infected Tissues.**—Werner writes from Czerny's clinic at Heidelberg to report research which has demonstrated that the radium rays not only kill bacteria, but also deprive them of toxic action. The toxicity is abolished without interfering with the property

of the bacteria to induce immunization. He found, further, that cells succumbing to the action of the radium rays are liable to develop bactericidal properties, much more pronounced than the ordinary autolytic processes. Rabbits were injected with cultures that had been killed by exposure to radium rays, and the results showed that the cultures must have been deprived of toxicity, as the animals could bear even two or three times the fatal dose of cultures killed by heat alone. At the same time it was found that the serum of the animals thus treated acquired unusually strong bacteriolytic and antitoxic powers. These results were obtained invariably in experiments with four staphylococcus stems, one streptococcus and one colon bacillus stem. No results were obtained in attempts to disinfect wounds with direct exposure to the radium rays. It was found, however, that necrosis induced by the radium rays was resistant to infection with germs later. The cells evidently became altered in some way under the influence of the radium rays so that they developed bactericidal properties without the co-operation of the leucocytes which were unable to penetrate into the necrotic patches.

96. **Hypertrophy of Muscles in Toxic Polyneuritis.**—Curschmann's first patient was a neuropathic and debilitated multipara with tobacco polyneuritis with paresis from long employment in a cigar factory. For four years there have been from six to eight recurrences during the twenty-four hours of cramps of the dorsal flexors of both feet, lasting from fifteen to thirty minutes. Gradually secondary hyperkinetic hypertrophy of the tibialis anticus developed, slightly involving the peroneus longus, with atrophy of other muscles. The reaction to electricity and other features of the case and of a similar one of alcohol polyneuritis are described. He can find only one case on record (Bressler's) exhibiting the same syndrome.

97. **Removal of Myomata During Pregnancy and Delivery.**—Thorn reports the details of 9 cases to show the extreme tolerance of the gravid uterus for myomectomy. He has observed 2 cases of axial torsion of the pregnant uterus due to the growth of myomata. The new growths were so close to the three months' ovum that abortion seemed almost inevitable when they were removed by a laparotomy, but the pregnancy continued to the eighth month, when a recently dead fetus was spontaneously delivered after a few days of hemorrhage, probably due to the abnormal attachment of the placenta. In the other case the four months pregnancy continued undisturbed to the end, after removal of a large myoma from the anterior wall of the uterus below the left cornu, and two smaller ones near by. The myoma was congested, with necrosis in the center. The symptoms compelling laparotomy in this case had come on suddenly, with violent abdominal pain, vomiting, etc. Central necrosis was also observed in another case presenting the same sudden onset of symptoms. One patient, known to have a myoma in the uterus, exhibited uncontrollable vomiting, requiring abortion, after which the myoma retrogressed one-half in size. His experience shows that it is impossible to foretell whether a myoma will make trouble during a pregnancy or not. One possible source of serious trouble is the giving out of the expelling force of the uterus on account of the presence of the myoma. In 2 of his patients the intestine must have become compressed, giving rise to excessive meteorism. The unfavorable action of very large myomata on the circulation and respiration is liable
to entail thromb tant treatment of delivery in case
of a complicatin hould carried too far. The
best plan is to ha tant surveillance in
a clinic, even aft obstacle. There
may be after-hem necrosis of the
myoma.

tube, an

both protected against injury through the walls of the Crookes' tube by the lead glass envelope. The small tube is of the proper length so that the Roentgen tube can never be brought too near the part exposed.

101. *Leukemia and Roentgen Treatments.*—Arneth has been making a careful study of the blood findings after exposure to the Roentgen rays, and analyzes all that has been published on the subject in Europe and Senn's article. His final verdict on the testimony thus offered to date is that the Roentgen rays have an undoubtedly favorable action in leukemia, but that it is indirect. They do not cure the lesions, but they destroy the parasites which are causing the lesions. The action of the Roentgen rays in leukemia is like that of quinin in malaria. Both cure the patient by killing off the microorganisms causing the trouble. This assumption entails the necessity for more thorough and more general exposure to the rays. They should be as extensive and as protracted as possible to seek out and destroy the causal germ in its remotest lurking places, not restricting the exposures, as in the past, to the blood-forming organs alone. This conception supplies, for the first time, an etiologic treatment for leukemia and one that is proving more successful than any in the past.

102. **Hay Fever.**—R. Mohr of Mügeln here summarizes the experiences of the "Association of Hay Fever Sufferers" who make their headquarters on the island of Helgoland during the hay fever season. He insists on the necessity for careful guarding against recurrence of the affection, expressing wonder that hay fever patients show so little common sense in this respect. Intoxication from pollen should be prevented. The hay fever sufferer should not take long walks or at least not without some protecting device, if no more than breathing through a handkerchief. Railroad trips should be avoided, and all exercise inducing sweating. The windows on the side toward the wind should be kept closed, especially at night, and all drafts should be avoided. The outer garments should not be kept in the living rooms, and no cut flowers should be allowed in them. The bedding and washing should not be aired or dried out of doors. Mohr has invented a little device which is worn in the nostrils and keeps out all pollen dust. Forty persons have been wearing this device during the last season, and those who have followed directions have been protected against hay fever. He is now perfecting a device for those who can not tolerate the sensation of a foreign body in the nose. The Dunbar hay fever specific remedies were used by members of the association with favorable results from the fluid pollantin in 87 cases, no results in 77, while 22 attributed the aggravation of their trouble to it. Operative measures did not seem to benefit but a very small proportion of the 138 persons thus treated, but the suprarenal extracts, applied locally by a physician, afforded relief in many instances. Mohr adds that the nose should always be rinsed out from the rear alone. Flight to a place where the pollen production has not yet begun or is past or is always scanty is still the best means to avoid hay fever in those predisposed to it.

Original Articles

CHRONIC ULCER OF THE STOMACH AND FIRST PORTION OF THE DUODENUM,

WITH ESPECIAL REFERENCE TO THE SURGICAL TREATMENT.*

WILLIAM J. MAYO, A.M., M.D.
Surgeon to St. Mary's Hospital.
ROCHESTER, MINN.

Chronic ulcer of the stomach is certainly a more frequent disease than clinicians would lead us to believe. Compare for a moment the results of autopsy findings with the clinical diagnosis on hospital admission. Take three hospitals in Philadelphia—Blockley Hospital, giving 1.42 per cent. as the result of autopsy finding; University Hospital, clinical findings 0.48 per cent.; Pennsylvania Hospital, clinical findings 0.13 per cent. (Francine). In other words, in two hospitals of exactly the same character in the same city, ulcer is found clinically nearly four times as often as in the other, while both fall short of the postmortem from 3 to 11 times. Bettman finds that a diagnosis of gastric ulcer was *made* but 24 times in 27,567 Cincinnati hospital admissions (.08 per cent.) Howard, in comparative tables, shows that New York City autopsy records give 1.42 per cent. of gastric ulcers, while the records of clinical admissions show only 0.44 per cent. Boston does better, autopsy 1.84 per cent., clinical 1.28 per cent. Francine says, "I entirely agree with Dr. Howard's statement that we can not base accurate or conservative conclusions on data obtained from clinical observation."

In 10,841 autopsies in 7 large American cities (Howard), the per cent. of gastric ulcers was 1.32, while in London it was 4.6 per cent. and in continental Europe 8.54 per cent. Welch gives 5 per cent. in 32,052 autopsies at Prague, Berlin, Breslau, Dresden, Erlangen and Kiel. There are two explanations of the greater apparent frequency of gastric ulcer in Europe than in America. One is that it is not apparent but real, and another, that the pathologic departments of European cities have for a long time been permanently established and postmortems are obligatory, while until of late years the work in American cities has been under changeable management and subjected to a variable personnel, also that consent of legal representatives must be obtained, and therefore autopsies are relatively much less frequent in this country. As showing the effect of searching with a definite purpose, Grunfeld of Copenhagen found 11 per cent. of gastric ulcers in 1,150 autopsies, and in the next 450, examined more carefully, found 20 per cent.

In regard to the relative frequency of gastric and duodenal ulcers, we have but few statistics. Francine found 38 cases of gastric ulcer in 2,830 autopsies, 2 duodenal, also 2 duodenal and gastric, practically only 10 per cent. of duodenal. As compared with surgical findings this is too small, and does not bear out the relative frequency shown by statistics of acute perforations. Moynihan in 22 cases of acute perforating ulcers found 15 gastric and 7 duodenal. Our experience with acute perforating ulcer is relatively smaller than with chronic ulcer. In 13 acute perforating ulcers 6 were gastric and 7 duodenal. Brunner collected 600 cases of acute perforation; of which one-fourth were duodenal. He also showed that 90 per cent. of acute perforating ulcers occur through the site of chronic ulcers and that diagnostic symptoms usually exist previous to perforation.

The duodenum above the opening of the common duct of the liver and pancreas is exposed to the same ulcer-producing causes that exist in the stomach, with the possible exception of traumatism; and as its tunics are thinner, it is even more readily affected by irritating secretions and ingesta. Statistics would seem to show that ulcer of the duodenum is a rare malady, but the data on which the supposition is based have been furnished either by postmortems or are the results of notoriously defective clinical examinations.

Postmortem study has certain disadvantages due to influences which have perhaps become active either shortly before or at the time of death, and which often mask the primary lesion and cloud the condition as it existed in life. Secondary changes and terminal infections may prevent a correct interpretation of the signs and symptoms which were manifested during the early stages of the disease—the curable period. This is shown by the revelations of surgery in appendicitis, extra-uterine pregnancy and cholelithiasis.

The same potent force is now at work in the field of ulcer of the stomach and duodenum, and the first fact which has been demonstrated is that those forms of ulceration which affect all the coats of the viscera and which by reason of their large size and thick, scar-like appearance can be easily demonstrated, are nearly as common in the duodenum as in the whole of the stomach. The postmortem statistics which have been gathered are certainly erroneous in their summing up as to the relative frequency of gastric and duodenal ulcer. The only conclusion which one can arrive at is that the examination was general and did not cover the duodenum with the same care that it did the stomach. The duodenum has received but little attention and therefore it was not subjected to close scrutiny during a general autopsy, especially as this particular feature was not in view at the time.

Admitting that clinical observation falls far short of the autopsy findings, in what way do results of surgical work compare with postmortem records? In 14 years Dr. Charles H. Mayo and myself have operated of the bacteria to induce immunization. He found, further, that cells succumbing to the action of the radium rays are liable to develop bactericidal properties, much more pronounced than the ordinary autolytic processes. Rabbits were injected with cultures that had been killed by exposure to radium rays, and the results showed that the cultures must have been deprived of toxicity, as the animals could bear even two or three times the fatal dose of cultures killed by heat alone. At the same time it was found that the serum of the animals thus treated acquired unusually strong bacteriolytic and antitoxic powers. These results were obtained invariably in experiments with four staphylococcus stems, one streptococcus and one colon bacillus stem. No results were obtained in attempts to disinfect wounds with direct exposure to the radium rays. It was found, however, that necrosis induced by the radium rays was resistant to infection with germs later. The cells evidently became altered in some way under the influence of the radium rays so that they developed bactericidal properties without the co-operation of the leucocytes which were unable to penetrate into the necrotic patches.

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

96. **Hypertrophy of Muscles in Toxic Polyneuritis.**—Curschmann's first patient was a neuropathic and debilitated multipara with tobacco polyneuritis with paresis from long employment in a cigar factory. For four years there have been from six to eight recurrences during the twenty-four hours of cramps of the dorsal flexors of both feet, lasting from fifteen to thirty minutes. Gradually secondary hyperkinetic hypertrophy of the tibialis anticus developed, slightly involving the peroneus longus, with atrophy of other muscles. The reaction to electricity and other features of the case and of a similar one of alcohol polyneuritis are described. He can find only one case on record (Bressler's) exhibiting the same syndrome.

97. **Removal of Myomata During Pregnancy and Delivery.**—Thorn reports the details of 9 cases to show the extreme tolerance of the gravid uterus for myomectomy. He has observed 2 cases of axial torsion of the pregnant uterus due to the growth of myomata. The new growths were so close to the three months' ovum that abortion seemed almost inevitable when they were removed by a laparotomy, but the pregnancy continued to the eighth month, when a recently dead fetus was spontaneously delivered after a few days of hemorrhage, probably due to the abnormal attachment of the placenta. In the other case the four months pregnancy continued undisturbed to the end, after removal of a large myoma from the anterior wall of the uterus below the left cornu, and two smaller ones near by. The myoma was congested, with necrosis in the center. The symptoms compelling laparotomy in this case had come on suddenly, with violent abdominal pain, vomiting, etc. Central necrosis was also observed in another case presenting the same sudden onset of symptoms. One patient, known to have a myoma in the uterus, exhibited uncontrollable vomiting, requiring abortion, after which the myoma retrogressed one-half in size. His experience shows that it is impossible to foretell whether a myoma will make trouble during a pregnancy or not. One possible source of serious trouble is the giving out of the expelling force of the uterus on account of the presence of the myoma. In 2 of his patients the intestine must have become compressed, giving rise to excessive meteorism. The unfavorable action of very large myomata on the circulation and respiration is liable to entail thrombosis. Expectant treatment of delivery in case of a complicating myoma should not be carried too far. The best plan is to have the woman under constant surveillance in a clinic, even after the head has passed the obstacle. There may be after-hemorrhage or trouble from necrosis of the myoma.

99. **Improved Roentgen Tube.**—Wichmann has his tubes made with a "lead glass" protecting mantle outside. A circular opening allows the focused rays to escape. The lead glass covering is continued to make a low wall around this opening, and a narrow metal tube with flaring top fits on this prolongation of the wall. The Roentgen rays are focused in the circular opening and can escape only through the narrow tube which is placed directly over the spot or introduced into the fistula or cavity to be treated. No rays escape except through the bottom of the tube, and the subject and the physician are both protected against injury through the walls of the Crookes' tube by the lead glass envelope. The small tube is of the proper length so that the Roentgen tube can never be brought too near the part exposed.

101. **Leukemia and Roentgen Treatments.**—Arneth has been making a careful study of the blood findings after exposure to the Roentgen rays, and analyzes all that has been published on the subject in Europe and Senn's article. His final verdict on the testimony thus offered to date is that the Roentgen rays have an undoubtedly favorable action in leukemia, but that it is indirect. They do not cure the lesions, but they destroy the parasites which are causing the lesions. The action of the Roentgen rays in leukemia is like that of quinin in malaria. Both cure the patient by killing off the microorganisms causing the trouble. This assumption entails the necessity for more thorough and more general exposure to the rays. They should be as extensive and as protracted as possible to seek out and destroy the causal germ in its remotest lurking places, not restricting the exposures, as in the past, to the blood-forming organs alone. This conception supplies, for the first time, an etiologic treatment for leukemia and one that is proving more successful than any in the past.

102. **Hay Fever.**—R. Mohr of Mügeln here summarizes the experiences of the "Association of Hay Fever Sufferers" who make their headquarters on the island of Helgoland during the hay fever season. He insists on the necessity for careful guarding against recurrence of the affection, expressing wonder that hay fever patients show so little common sense in this respect. Intoxication from pollen should be prevented. The hay fever sufferer should not take long walks or at least not without some protecting device, if no more than breathing through a handkerchief. Railroad trips should be avoided, and all exercise inducing sweating. The windows on the side toward the wind should be kept closed, especially at night, and all drafts should be avoided. The outer garments should not be kept in the living rooms, and no cut flowers should be allowed in them. The bedding and washing should not be aired or dried out of doors. Mohr has invented a little device which is worn in the nostrils and keeps out all pollen dust. Forty persons have been wearing this device during the last season, and those who have followed directions have been protected against hay fever. He is now perfecting a device for those who can not tolerate the sensation of a foreign body in the nose. The Dunbar hay fever specific remedies were used by members of the association with favorable results from the fluid pollantin in 87 cases, no results in 77, while 22 attributed the aggravation of their trouble to it. Operative measures did not seem to benefit but a very small proportion of the 138 persons thus treated, but the suprarenal extracts, applied locally by a physician, afforded relief in many instances. Mohr adds that the nose should always be rinsed out from the rear alone. Flight to a place where the pollen production has not yet begun or is past or is always scanty is still the best means to avoid hay fever in those predisposed to it.

CHRONIC ULCER OF THE STOMACH AND FIRST PORTION OF THE DUODENUM,

WITH ESPECIAL REFERENCE TO THE SURGICAL TREATMENT.*

WILLIAM J. MAYO, A.M., M.D.
Surgeon to St. Mary's Hospital.
ROCHESTER, MINN.

Chronic ulcer of the stomach is certainly a more frequent disease than clinicians would lead us to believe. Compare for a moment the results of autopsy findings with the clinical diagnosis on hospital admission. Take three hospitals in Philadelphia—Blockley Hospital, giving 1.42 per cent. as the result of autopsy finding; University Hospital, clinical findings 0.48 per cent.; Pennsylvania Hospital, clinical findings 0.13 per cent. (Francine). In other words, in two hospitals of exactly the same character in the same city, ulcer is found clinically nearly four times as often as in the other, while both fall short of the postmortem from 3 to 11 times. Bettman finds that a diagnosis of gastric ulcer was *made* but 24 times in 27,567 Cincinnati hospital admissions (.08 per cent.) Howard, in comparative tables, shows that New York City autopsy records give 1.42 per cent. of gastric ulcers, while the records of clinical admissions show only 0.44 per cent. Boston does better, autopsy 1.84 per cent., clinical 1.28 per cent. Francine says, "I entirely agree with Dr. Howard's statement that we can not base accurate or conservative conclusions on data obtained from clinical observation."

In 10,841 autopsies in 7 large American cities (Howard), the per cent. of gastric ulcers was 1.32, while in London it was 4.6 per cent. and in continental Europe 8.54 per cent. Welch gives 5 per cent. in 32,052 autopsies at Prague, Berlin, Breslau, Dresden, Erlangen and Kiel. There are two explanations of the greater apparent frequency of gastric ulcer in Europe than in America. One is that it is not apparent but real, and another, that the pathologic departments of European cities have for a long time been permanently established and postmortems are obligatory, while until of late years the work in American cities has been under changeable management and subjected to a variable personnel, also that consent of legal representatives must be obtained, and therefore autopsies are relatively much less frequent in this country. As showing the effect of searching with a definite purpose, Grunfeld of Copenhagen found 11 per cent. of gastric ulcers in 1,150 autopsies, and in the next 450, examined more carefully, found 20 per cent.

In regard to the relative frequency of gastric and duodenal ulcers, we have but few statistics. Francine found 38 cases of gastric ulcer in 2,830 autopsies, 2 duodenal, also 2 duodenal and gastric, practically only 10 per cent. of duodenal. As compared with surgical findings this is too small, and does not bear out the relative frequency shown by statistics of acute perforations. Moynihan in 22 cases of acute perforating ulcers found 15 gastric and 7 duodenal. Our experience with acute perforating ulcer is relatively smaller than with chronic ulcer. In 13 acute perforating ulcers 6 were gastric and 7 duodenal. Brunner collected 600 cases of acute perforation; of which one-fourth were duodenal. He also showed that 90 per cent. of acute perforating ulcers occur through the site of chronic ulcers and that diagnostic symptoms usually exist previous to perforation.

The duodenum above the opening of the common duct of the liver and pancreas is exposed to the same ulcer-producing causes that exist in the stomach, with the possible exception of traumatism; and as its tunics are thinner, it is even more readily affected by irritating secretions and ingesta. Statistics would seem to show that ulcer of the duodenum is a rare malady, but the data on which the supposition is based have been furnished either by postmortems or are the results of notoriously defective clinical examinations.

Postmortem study has certain disadvantages due to influences which have perhaps become active either shortly before or at the time of death, and which often mask the primary lesion and cloud the condition as it existed in life. Secondary changes and terminal infections may prevent a correct interpretation of the signs and symptoms which were manifested during the early stages of the disease—the curable period. This is shown by the revelations of surgery in appendicitis, extra-uterine pregnancy and cholelithiasis.

The same potent force is now at work in the field of ulcer of the stomach and duodenum, and the first fact which has been demonstrated is that those forms of ulceration which affect all the coats of the viscera and which by reason of their large size and thick, scar-like appearance can be easily demonstrated, are nearly as common in the duodenum as in the whole of the stomach. The postmortem statistics which have been gathered are certainly erroneous in their summing up as to the relative frequency of gastric and duodenal ulcer. The only conclusion which one can arrive at is that the examination was general and did not cover the duodenum with the same care that it did the stomach. The duodenum has received but little attention and therefore it was not subjected to close scrutiny during a general autopsy, especially as this particular feature was not in view at the time.

Admitting that clinical observation falls far short of the autopsy findings, in what way do results of surgical work compare with postmortem records? In 14 years Dr. Charles H. Mayo and myself have operated in nearly 800 cases of stomach and duodenal disease. Eliminating gastric cancers and all other cases in which the necessity for operation did not immediately arise from ulcer, we have 384 operations for gastric ulcer and its results, and 84 operations for duodenal ulcer, or about 78 per cent. gastric and 22 per cent. duodenal; but this is not fair to the duodenal disease, because it has only been within a short time that we have recognized duodenal ulcers and many of our earlier cases marked pyloric, may have been an extension from the duodenum. We have thought it wise to narrow the limits of this study to a consideration of only the last two and one-half years, from Jan. 1, 1903, to July 1, 1905, and also to consider only the cases subjected to gastrojejunostomy, excluding all of the ulcers excised or subjected to Finney's operation, pyloroplasty, etc. This gives us 231 cases, 119 males and 112 females, of which 158 were gastric, 60 duodenal and 14 duodenal and gastric; 20 of the duodenal ulcers extended up to and involved the pylorus. In other words, out of 231 gastric and duodenal ulcers, the duodenum was involved 74 times; 55 times in males and only 19 in females.

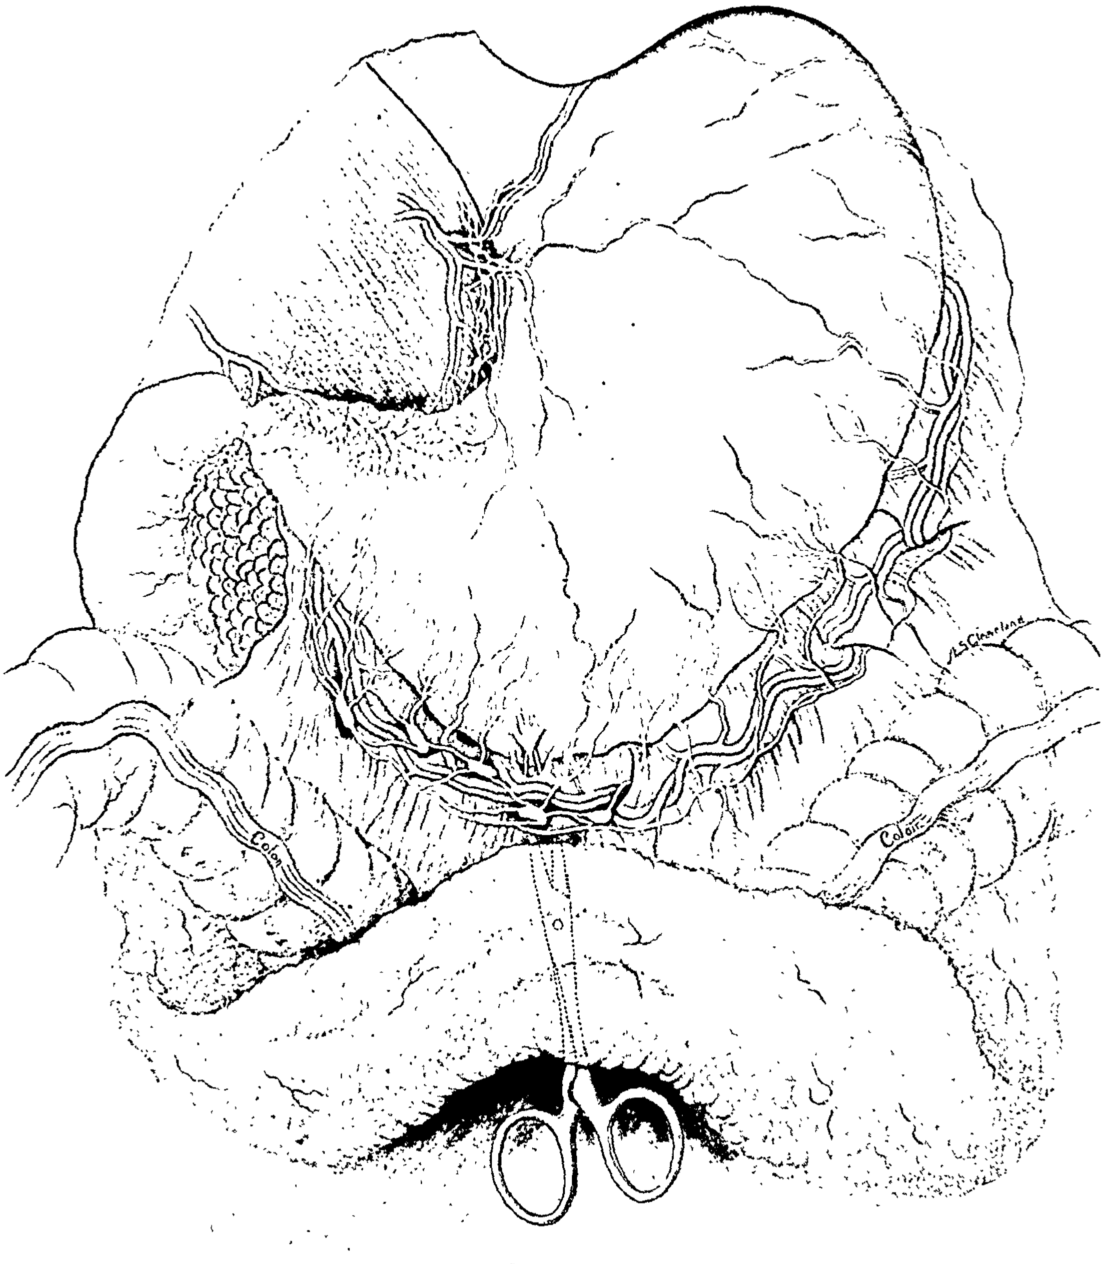

Fig. 2.—Showing forceps passed through from behind and grasping anterior gastric wall near the greater curvature at the lowest point. Saddle ulcer of lesser curvature near pylorus.

CLASSIFICATION OF GASTRIC AND DUODENAL ULCERS.

For clinical purposes I will classify in 2 groups, the *indurated* and the *non-indurated*, all the ulcers operated on: First, the *indurated* ulcer, which involves all the coats of the organ and which usually shows evidences of cicatrization in some part of its extent. The diseased area is a thick, milky-white patch, easily identified from without the gastric or duodenal wall. In the stomach it involves the pyloric portion in the great majority of cases, frequently saddle-shaped, riding the lesser curvature and extending flap-like down the anterior and posterior walls. In such cases the pyloric portion beyond is usually thickened and gives rise to more or less obstruction, even if not actually involved in the ulcerative process. In about 20 per cent., more than one ulcer was found. In the duodenum the first 2½ inches are always involved well above the entrance of the common duct with its alkaline discharges, and the ulcer extends up to the pylorus or within ¾ of an inch of it. In only 3 instances could more than one duodenal ulcer be shown. Sixty-eight of the 74 duodenal ulcers were of the indurated variety, and 151 of the total 231 cases of duodenal and gastric ulcers were so classified. Of these 95 were males and 56 females.

Seymour Taylor in 100 cases found 72 males and 28 females. Associated with this group of indurated ulcers are benign, pyloric obstructions of inflammatory origin, hour-glass stomachs, adhesions and deformities arising from protected chronic perforations.

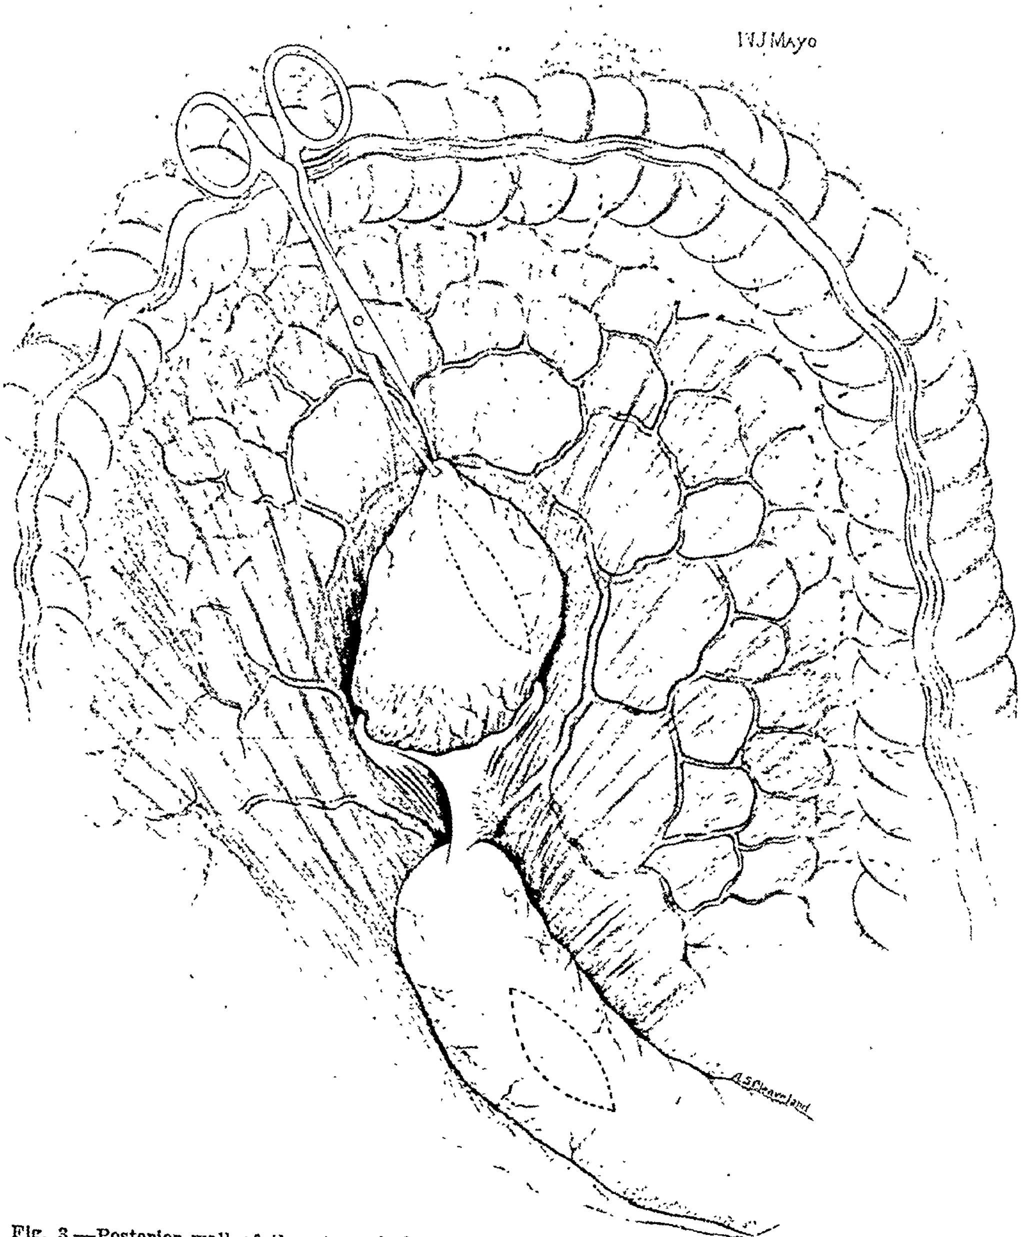

Fig. 3.—Posterior wall of the stomach drawn through opening torn in transverse meso-colon. Forceps still marking low point. Dotted lines on stomach and jejunum show situation of proposed anastomosis.

The second variety I have designated the *non-indurated* ulcer. They have also been termed medical or clinical ulcers, because although they give undoubted evidence of the disease there is nothing to show the ulcer site from the exterior of the stomach upon operation. The reason for this is that the lesion involves only the mucous coat. In some cases a little thickening can be discovered (Mikulicz) or a little glueing of the mucous to the muscular coats, preventing the normal slipping of one on the other (Moynihan). But in the typical case prolonged search of the interior of the stomach may be necessary to find the diseased process. Many an individual has bled to death from an ulcer so minute that it could only be found with the microscope. Bramwell says that many of these cases heal so minutely that no evidence can be found at autopsy.

We have had a number of cases come to operation after years of trouble—hemorrhages, stagnation and retention of food, etc.—who were cured by operation but in whom no sign of ulcer could be shown on the exterior of the stomach. In some instances we have opened and searched the interior of the gastric cavity to find an ulcer from which the patient had bled repeatedly and within a short time but we have not always found it. It is possible, or indeed probable, that in some of these patients an indurated ulcer may have existed in a situation not accessible to palpation or inspection.

Non-indurated ulcers are of two varieties: (a) The mucous erosion of Dieulafoy in which only the superficial epithelial layers of the mucous membrane are involved, and (b) the typical, round, peptic and fissure ulcer. In our experience the fissure-like ulcer has been of frequent occurrence. In one subject bleeding at the time of operation was found to proceed from a small fissure which could only be detected by bending the mucous membrane sharply, the little defect showing as the weave would show on folding a piece of velvet. Eighty of the 231 cases belong to this group of non-indurated ulcers, 56 being females and 24 males. One interesting diagnostic feature was first pointed out by Lund. He noted that an ulcer could sometimes be located by an enlarged "sentinel" gland in the omentum, tributary to the lesion. We have verified this in a number of cases.

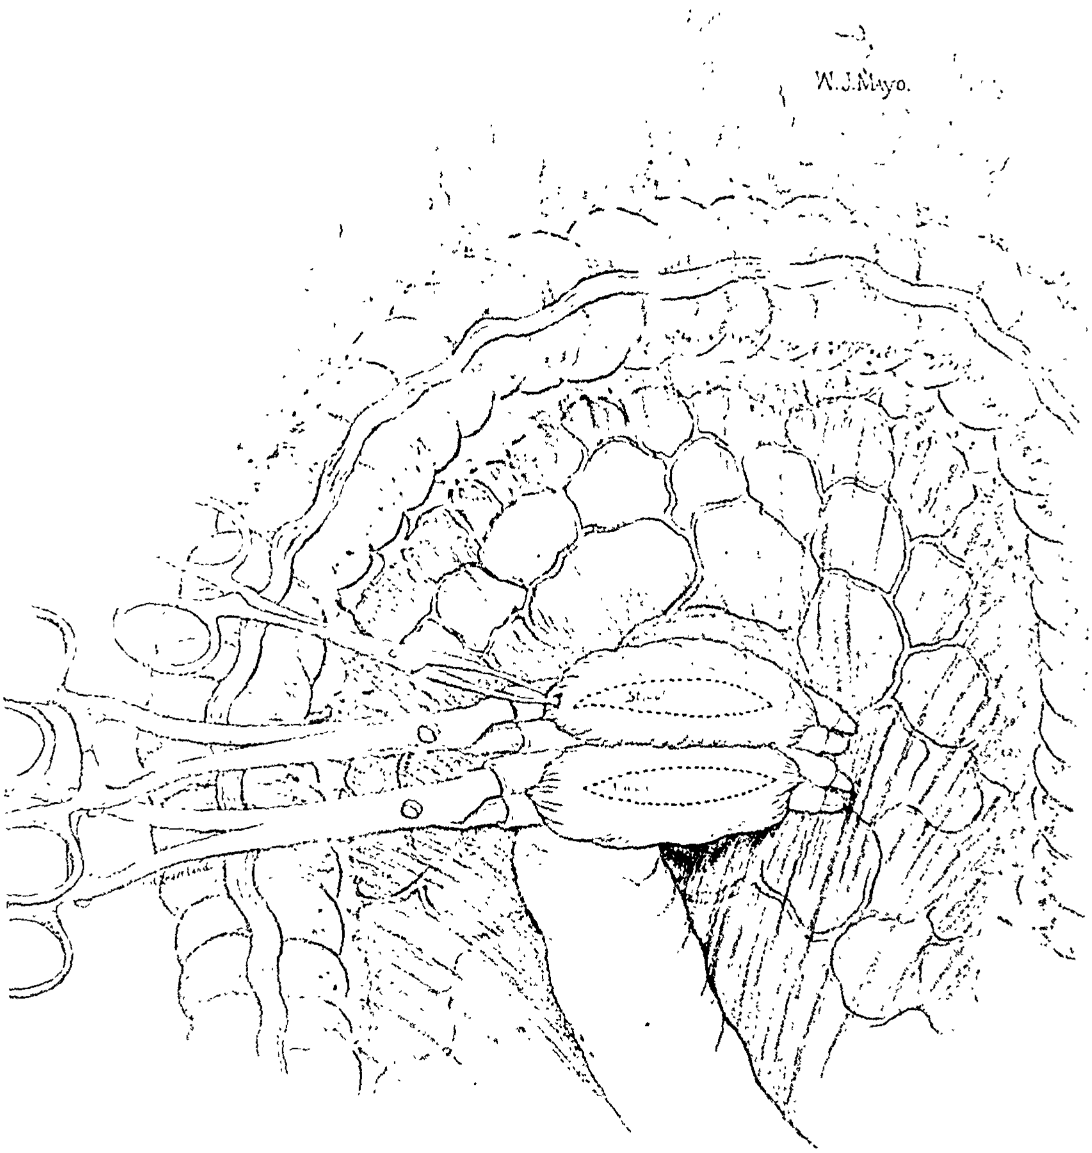

Fig. 4.—Stomach and jejunum drawn into clamps for suturing. Small forceps still marking low point of stomach.

We have noted for a long time that in nearly all open ulcers the tributary lymphatic glands were definitely enlarged to the size of a *Lima bean, from one centimeter to one and a half centimeters in diameter, usually in the* gastro-colic omentum; in this respect being unlike cancer, which affects the glands of the lesser *curvature* by preference. The enlargement is soft and shows simple adenitis. It is probable that this may be a valuable diagnostic sign, and that we should find enlarged glands in all cases of ulcer, mucous or otherwise. The value is somewhat lessened because we have seen adenitis in the same situation in cases of *cholecystitis*; *but in these* cases enlarged glands were also found along the common duct.

The question of non-indurated ulcer needs further elucidation. The very fact that the condition may not be cleared up at the operating table prevents us from gaining in wisdom by the experience. We know that the

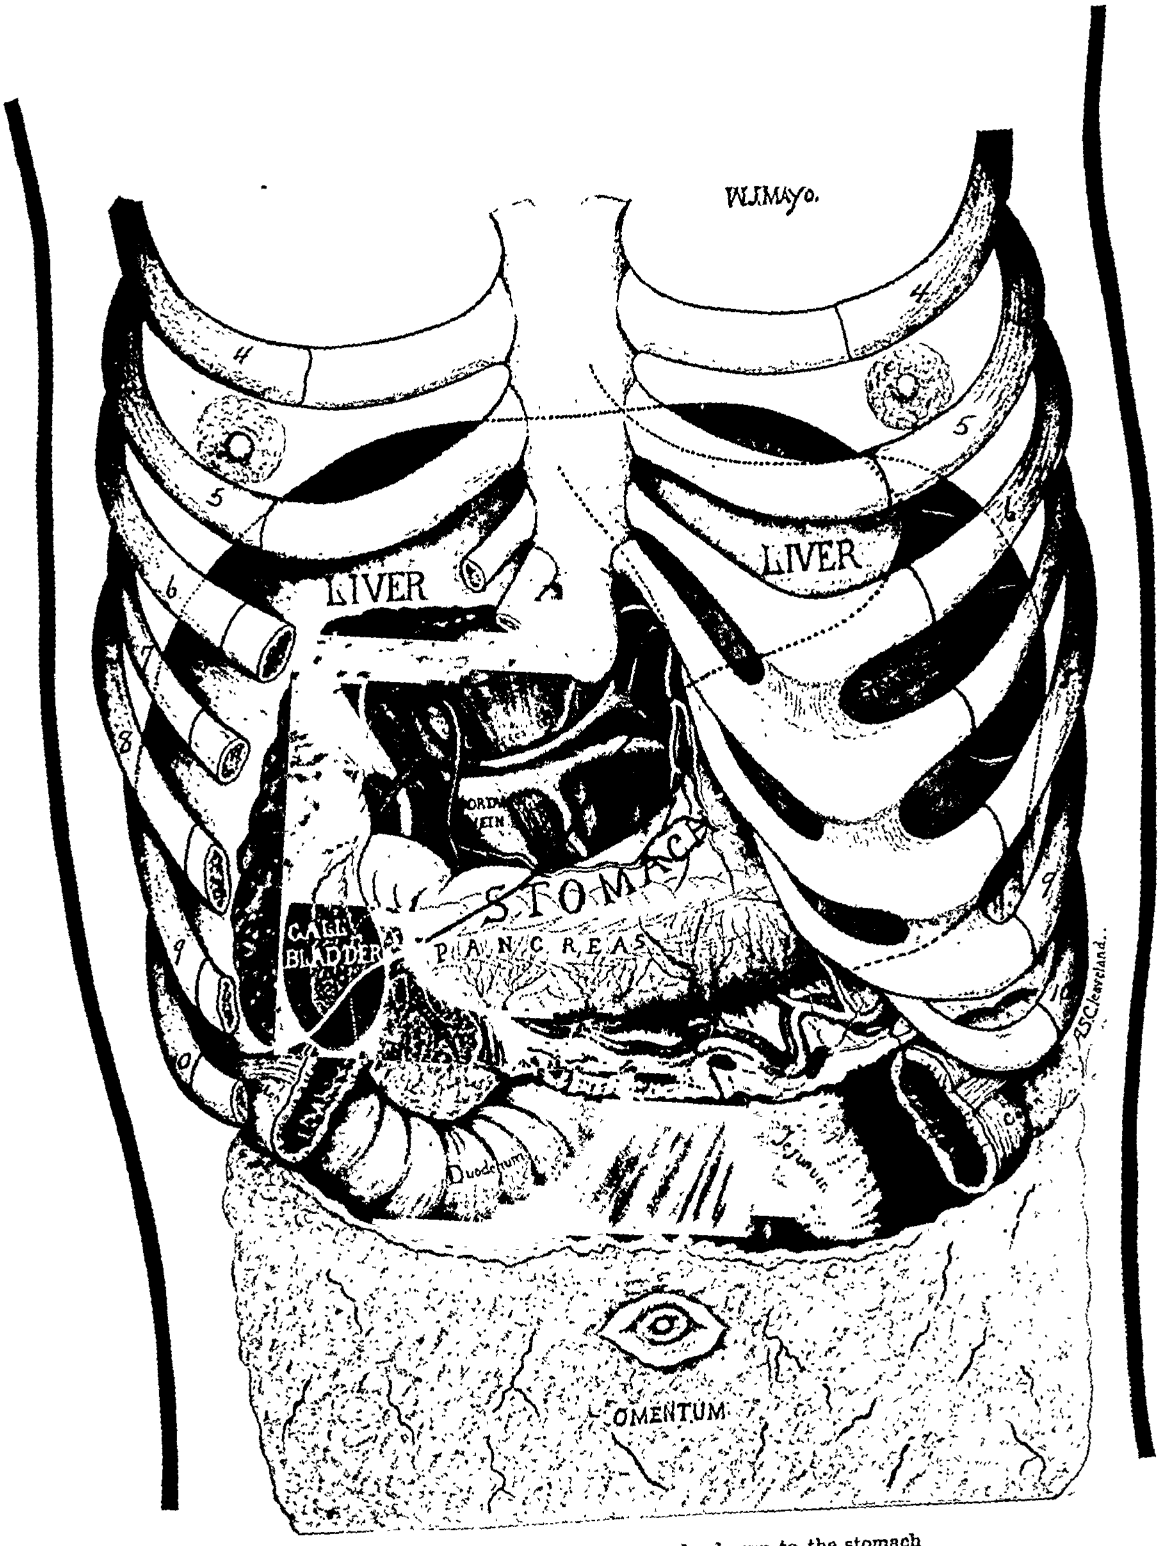

Fig. 1—Shows relation of the duodenum to the stomach

Supplement to
The Journal of the American Medical Association

Illustrating Dr. Mayo's Article on "Gastr

majority of well-selected subjects recover definitely; but a minority give less favorable results, and operating for purely medical indications leads to unscientific and at times indiscriminate resort to operation. Especially is this true of that vast army of neurasthenics with gastric symptoms depending on a neurosis; a complaint simulating ulcer, a prolapsed, splashy stomach, a too ready diagnosis followed by an ill-advised gastroenterostomy. The fact that the stomach appears to be normal is explained by the known inability always to locate a mucous ulcer. This is not a fanciful nor overdrawn picture. There is seldom a week but several such cases present themselves at our clinic and are refused operation. Many of them have already had their movable organs fixed (kidney and uterus) and the removable ones removed (ovaries, appendix, etc.), and now are anxious to secure relief by a further resort to the knife. That such cases are frequently operated on can not be questioned, and that they will tend to bring surgery of the stomach into disrepute is equally certain. The so-called atonic dilatations are not often greatly benefited by operation unless there is marked and persistent delay of food in the stomach. This group is closely allied to the neurasthenic class, and the individual case must be carefully considered, with a prejudice against operation unless it can be clearly shown to be indicated. Fortunately, the field of gastric surgery is too large for a few of these unfortunate instances to affect the general results, but I would urge on the profession the necessity of eliminating the neurasthenic from the field unless the signs and symptoms of ulcer are distinct. Of course the nervous condition is no valid reason for refusing to relieve actual disease.

There are some problems closely related with the nonindurated ulcer which are but little understood, and one of the most important of these is pyloric spasm. The *x*-ray experiments of Cannon have been very interesting in this connection, showing that the fundus of the stomach is the storehouse where maceration takes place, and the muscular, pyloric end the active agent in kneading the ingesta into a homogeneous whole. Numerous observations at the operating table have convinced us that pyloric spasm is not due to a contraction of the pyloric sphincter alone, but of any part or all of this end of the stomach.

There is undoubtedly, also, such an entity as chronic contraction of the pyloric muscle without actual demonstrable lesion, and in such a degree as to be the only evident cause of gastric dilatation, stagnation of food and chronic distress. A serious form of interference with gastric motility has been noted by Ochsner, Finney, Munro and others, as well as by myself, in which there is chronic dilatation of the stomach and duodenum as far as the common duct of the liver, giving rise to many of the symptoms of obstruction. Ochsner believes this condition is due to a pathogenic contraction of a normal excess of muscle in the second portion of the duodenum, which he has demonstrated anatomically. Another variety of interference with gastric motility is the not rare condition of "valve formation," in which a high lying pylorus is held taut by a short gastrocolic omentum. I have met with a small number of such cases, three of which were reported before the surgical section of the American Medical Association at Atlanta, May, 1896.

From our personal experience no conclusions can be drawn, but at present we do not advise operation in any case of acute ulcer, although certain complications such as perforation, hemorrhage and grave obstruction may compel its speedy performance. We do not advise operation in chronic ulcer or its associated diseases until careful and prolonged medical treatment has failed to permanently cure, and we strongly advise against operation in neurotic individuals with prolapse of the stomach. We advise operation in all cases of stagnation and retention of food depending on mechanical causes such as pyloric obstruction, and in cases of exhausting hemorrhages. We advise and practice operation in that considerable group of chronic cases with acute exacerbations, in whom frequent relapses with their attendant disabilities prevent the patient from the enjoyment of good health. It is this latter group which reminds us forcibly of the early days of appendicitis in which great divergence of opinion was made manifest, from the practitioner who rarely saw a case to the equally honest man who saw them frequently but always cured them without trouble. We have gone through the same controversy as to the surgical treatment of gallstones and other diseases.

There are a number of careful observers who predict that the ultimate field of gastric surgery will be small, and that the diagnosis of surgical conditions can not often be made; but this was equally true of the early days of appendicitis, of gallstone disease and of pyosalpinx.

I think no unprejudiced person can doubt the conclusion that gastric and duodenal ulcers and associated disorders are more frequent maladies than we have been led to believe, and also that ulcer or some of its numerous complications, may and often does produce a train of symptoms which medicine is powerless to cure permanently.

What percentage of gastric and duodenal ulcers may be expected to be cured by medical means? Five hundred cases treated medically in the London Hospital in the five years from 1897 to 1902 gave a percentage of 18 for the death rate, and 42 per cent. were not cured at the time of discharge. As 211 of the 500 had been cured one or more times of previous attacks, who can predict the future history of the 40 per cent. discharged as cured?

Greenough and Joslin, of the medically treated ulcers in the Massachusetts General Hospital, showed that only 55 per cent. were discharged as cured, and 56 per cent. of these supposed cured were dead or still suffering at the time the report was made, five years later. Mumford reports only 4 per cent. of gastric dilatations resulting from ulcer, as cured medically, out of 122 cases in the Massachusetts General Hospital. Russell's statistics, derived from a large number of out-patients, show that 42.6 per cent. of gastric ulcers recovered; but as it was the first attack in 27.7 per cent. and might therefore be called acute, this gives a recovery of only 14.9 per cent. of the chronic cases. The balance either died or continued to suffer (Blake). Munro well remarks, "Is it surprising that an increasing number of ulcer subjects are spontaneously seeking surgical relief?"

It is wise to be conservative and to compel each new departure to bring its own proof. What results can surgery show in this field? First, it has demonstrated the clinical frequency of ulcer of the stomach and duodenum, not a *new* thing, because it has been shown for years in the autopsy records as already pointed out; second, it has developed a symptomatology which enables the diagnosis to be made, and has demonstrated the operative curability of ulcer and certain associated disorders. Surgery has brought back to a safe ground a large number of ulcer victims who, after repeated medical cures had taken to fakers, patent medicine venders, christian (?) science (?) or were making the best of their condition and using patent foodless foods and a restricted diet. In doing even this much, surgery has been open to sound criticism, first on the occasional selection of an unfortunate case for operation, and second on the occasional unsatisfactory results of operative interference both as to mortality and permanence of cure. It is the surgeon's duty to overcome this prejudice by furnishing better results.

The history of successful gastric surgery is not more than five years old, and the best of it not over two years' duration. The medical man must discard the older statistics as to technic and mortality which have become merely venerable relics, and do not at all represent advanced surgical thought on the subject. It is certainly discouraging to turn to the newer works on medicine and find not the slightest attempt made to show the advance which surgery has made, and the question of surgical relief being arbitrarily determined by the achievements of two decades ago.

Surgery is essentially mechanical and must benefit the patient in a mechanical way to a large extent (Fig. 1). Most surgical questions connected with chronic ulcer arise from interference with good stomach drainage, either by actual obstruction or by muscular spasm, so that the food and secretions are subjected to delay in that part of the stomach lying to the left of the pyloric muscular portion (the pyloric portion is that part covered by the lesser curvature), and the method of relief which has the largest field of usefulness consists of gastrojejunostomy made on a line perpendicular with the cardiac orifice of the stomach (Fig. 2). This will usually be found to be the most dependent portion. The opening must be placed on the posterior wall, at the very bottom of the gastric cavity, and should extend anteriorly ¼ inch, so that the jejunum is mortised on to the stomach (Fig. 2). The line of the gastric opening should be that of Moynihan, oblique from above down and left to right (Fig. 3). The jejunum should be anastomosed within three inches of its origin (Fig. 3) so that there shall be no loop (Fig. 4). After an experience of somewhat over 500 gastroenterostomies, including gastroduodenostomies and pyloroplasties, we have come to Peterson's conclusion, that the loop has been responsible for the greater part of the evils arising after gastrojejunostomy, such as biliary regurgitant vomiting (vicious circle). The intestine should be secured so high that there can be little loss of nutrient absorbents. The straight drop of the bowel gives protection against secondary jejunal ulcer by the constant presence of the alkaline biliary and pancreatic secretions, and also adds to the security against future complications. There is no doubt that contraction of the opening is less liable to take place if there is no loop to make traction. As to mortality, we have had less than 3 per cent. mortality in our last 150 suture operations, and in the last 81 cases of benign disease there has been but 1 death. These results are no better than those of Ochsner, Murphy, Munro, Deaver and others in this country, and Robson. Moynihan, Mikulicz, Kocher, Hartman and others abroad.

The operation here advocated has given us better results than any other which we have tried, but we have had two cases of chronic bile regurgitation occur, evidently due to faulty technic. In both patients there has been great relief of the original symptoms and in neither has the complication as yet been of sufficient moment to require a second operation.

Next to gastrojejunostomy, the operation of gastroduodenostomy, devised by Finney, is of the greatest value. It is especially suited to narrow strictures. In open ulcer it does not drain the stomach to the proximal side of the muscular pyloric region, and the food must still pass into the ulcer area to reach the outlet. The pyloroplasty of Heinke Mikulicz is now but little practiced and the method of closure is of the utmost importance after an ulcer is excised. As a matter of fact, the pyloroplastic principle has been one of the great factors in modern plastic surgery. The operation of Rodman, consisting of a complete excision of the entire ulcer-bearing muscular pyloric end of the stomach, with independent gastrojejunostomy, will gain ground in the future. Graham has found a good precancerous history of ulcer or associated disorders in 36 per cent. of our operated cases of cancer of the stomach, and clear evidence of cancer development on ulcer in 30 per cent. of the last 40 pylorectomies and partial gastrectomies; certainly an argument for the radical operation. Excision of the ulcer may be of value in a small group of cases if there be no obstruction and one is sure that only one ulcer exists.

Admitting that the technic and mortality of gastric surgery is satisfactory, have the patients been relieved? Excluding some cases of bad selection, I can conscientiously say that we are doing no kind of surgery to-day which gives more pleasing results in properly selected subjects than in the field of chronic gastric and duodenal ulcer and associated disorders. The disappointments have been due to inability to secure and maintain good stomach drainage through imperfect technic, rather than failure of a properly executed operation to relieve. While gastrojejunostomy has the largest field of usefulness, we must not look upon it as a cure-all. It is purely a drainage operation. If the stomach is not dilated and the pylorus be unobstructed, the food will continue to pass out the normal outlet and the patient will not be benefited. For this reason, indurated ulcers with definite mechanical lesions give far better results than non-indurated ulcers in which obstructions are not found, and it is this latter group which gives a considerable percentage of secondary operations and complications. We can not agree with the opinion which has recently been advanced that gastrojejunostomy should be done almost regardless of the condition present. There is nothing mysterious about this valuable operation. It permits retained secretions and ingesta to readily escape. If motility is normal it has little function.

In conclusion let me call your attention to the vast importance of this subject as it enables us to differentiate the benign from the malignant diseases of the stomach. Nearly one-third of all cancers in the human body are in the stomach. In 70 cases in which we have excised a large part of the stomach, we have had 4 cancer cases live more than three years, 3 are still alive and without return. We have a number alive over two years and the majority live a year. The average mortality was 12 per cent., and in the last 40 cases with the technic published in the *Annals of Surgery*, March, 1904, there were but 2 deaths, a mortality of 5 per cent.

Note.—We are often questioned as to the reasons why we have so many stomach operations up in the Northwest. As a matter of fact, these cases represent residents of 26 states and Canada; a little less than 20 per cent. belong to Minnesota.

THE EARLY DIAGNOSIS OF GASTRIC ULCER.*

H. D. NILES, M.D.,
SALT LAKE CITY, UTAH.

For a long time hemorrhage, obstructive vomiting and a certain characteristic localized pain were regarded as the essential symptoms of gastric ulcer, and when these classical symptoms were absent this lesion was diagnosed and treated (or mistreated) under other and various names that rarely conveyed any idea of the real causative pathology. In the light of our present knowledge, we must believe that our firm but unfounded faith in these diagnostic tests excluded from rational treatment a large majority of all our cases and persuaded us to make chronic gastritis, gastralgia and dyspepsia responsible for much suffering and not a few deaths that should properly be charged to gastric ulcer.

It was not until the recent advances in stomach surgery permitted us often to observe and study gastric ulcer in life on the operating table that we were made to realize the great frequency and grave importance of this lesion. And it was not until an efficient and promising treatment was developed that the great practical need of making an early diagnosis was felt. Since then we have all been striving to evolve some methods of diagnosis that would not allow a large percentage of our cases to escape early recognition and rational treatment.

Thus far no single symptom or laboratory test has proven sufficient, and until some such infallible indication is discovered we must depend largely one our interpretation of groups of symptoms and our willingness to resort, when necessary, to the exploratory incision.

In determining the relative value of each symptom, or group of symptoms, and in deciding on the indications for an exploratory operation, I believe we must trust to the study and comparison of the early clinical histories of gastric ulcers actually seen in life on the operating table. From our accumulated recorded experiences we may hope ultimately to work out the solution of this problem in diagnostics.

Without any pretense of giving statistical information, I shall crystallize into the fewest possible words the conclusions suggested by my observations in thirty-nine cases and my experience with thirty-six cases. In each of these seventy-five cases I was able to secure the early and later clinical history and to note the actual conditions revealed during the operation.

In sixty-six of these patients (88 per cent.) the initial symptoms were those that might easily be attributed to any mild digestive disturbance. In the remaining nine patients hemorrhage, perforation, acute vomiting, or periodic attacks of intense pain occurred early, and should have insured an early recognition of the real pathology. The average time from the appearance of the first symptom until operation was done was eight years. In five cases which undoubtedly began as ulcer, cancer developed before operative measures were undertaken, and in other cases delay in operation prevented an absolutely perfect result on account of irreparable structural changes. I think, therefore, we may fairly assume that an early diagnosis and prompt rational treatment might in this series of cases have prevented a total of 600 years of suffering, saved five patients from the apprehension of recurring malignant disease, and have secured a comparatively perfect result in each case.

In the face of such figures (and I believe my experience is not very different from that of most operators) no thoughtful student can fail to be impressed with the new and grave responsibility that falls to the diagnostician to-day whenever he is confronted by a patient suffering from any obscure disease of the stomach, however mild the symptoms may be.

In the early stages of at least 85 per cent. of gastric ulcers, none of the generally recognized typical symptoms are present and a diagnosis may seem impossible. It often happens, too, that neither the physician nor the patient is impressed with the serious consequences of delay in determining the causative pathology and no special effort is made to do so until the more suggestive symptoms arise. In spite of these difficulties, I think there are diagnostic aids that may guide us to an early and correct conclusion in the majority of these obscure cases.

First: In making a differential diagnosis, I think we should take into consideration the frequency of ulcer as compared with other stomach lesions. We should remember that the physiologic functions and the anatomic structure and relations of the stomach render it especially susceptible to ulceration, and that on the postmortem table, as well as in the operating room, ulcer is found more frequently than all other pathologic lesions of the stomach combined. Indeed, it is estimated that not less than 5 per cent. of the human race are afflicted at some period of their lives with gastric ulcer. This knowledge of the relative frequency of ulcer should not only be accepted as a proved theory in our libraries, but it should be applied in the consulting room and at the bedside in weighing the evidence for or against gastric ulcer.

Second: We should remember the influence of age, trauma and habits on the development of this pathology. The average age of patients operated on was 41; the greatest number was between 38 and 48 years old; the next greatest between 18 and 28, and the fewest between 28 and 38. Hence I am led to believe that the two periods in which stomach ulcer is most likely to occur and to produce urgent symptoms are either during the years of most rapid development or near the age that degenerative changes begin. During the intervening period the ulcer is frequently quiescent. The age of the patient is therefore significant, and should be taken into consideration in estimating the probability of ulceration. Thirty-five of the patients were male and forty female, not enough difference to merit consideration.

Of the patients operated on between the ages of 18 and 28 years, few led very active lives, while the reverse was true of those operated on past middle life. Many in the latter class engaged in rather violent exercise, such as horseback riding, etc. My observations would lead me to believe that trauma or any exercise that holds the stomach in a strained or immobile position may be a rather important factor in the production of ulcer, especially in the middle aged. The young rarely give a previous history that is suggestive; the middle aged, on the contrary, either refer to attacks of pain in early life or we find their distress is associated with trauma or habits or work or exercise that may be an exciting cause. In this way the occurrence of duodenal ulcer after an extensive burn may be explained on the ground that the stomach and duodenum are involuntarily held in a strained or immobile position a long time.

Third: We can and should narrow the field of di ferential diagnosis by excluding other possible constitutional and local causes of the symptoms.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Fourth: We will eliminate this most common source of error if we remember that gastritis, indigestion and gastralgia are the most constant results, and hyperacidity the most common cause of gastric ulcer. Hence all the symptoms of gastritis, gastralgia and so-called dyspepsia may have an ulcer as a primary cause, while hyperacidity, if persistent, points strongly to the existence or the coming of an ulcer. At least those of us who believe that ulcer of the stomach, like ulcer in other parts of the body, depends usually on local causes, must also consider that the digestive properties of the *normal* gastric juice can only produce local necrosis where a part of the stomach wall is immobilized by adhesions or muscular spasm, or is partially devitalized by the presence of an old cicatrix or by infected emboli carried by the vascular omentum from remote or nearby intraperitoneal infection, such as a gall-bladder, appendiceal or pelvic, inflammation might furnish. As these conditions do not prevail often it is fair to assume that in a majority of cases the fault lies in the exaggerated corrosive or excessive digestive properties of the gastric juice and is not due to any previous defect in the stomach walls. It may be said further that so far as examinations of the gastric contents have been made in the early stages of gastric ulcer, then tend to confirm the belief that hyperacidity is by far the most common cause of ulcer and that it is certainly one of the most significant symptoms.

Fifth: We should attach importance as to whether or not the continuance of the symptoms is favorably influenced by *medicinal or dietetic measures. In other* words, if the stomach ailment is of long duration or occurs or recurs without apparent cause, it is probably due to a real pathology, rather than to a transient functional disturbance, and the causative factor is most likely to be ulcer. Hyperacidity associated with chronicity points strongly to ulcer.

Sixth: It may help us to recall that the ulcer that occurs in the period of most rapid development (that is between 18 and 28 years) is nearly always due to hyperacidity alone, and often cicatrizes with proper treatment or even without treatment; while the ulcer that is found in patients past middle age is more likely to be due to degenerative changes in the scar of an old ulcer that may have been quiescent for years, but which when the reparative powers of nature begin to decline is likely to remain open and give serious trouble unless relieved by surgical measures. The first form of ulcer is due to an imperfect adjustment of the secretory functions, and the last to Nature's inability to protect scar tissue from the digestive effects of the normal gastric juice. In this connection the rule holds good that any inflammatory lesion of the alimentary canal when confined to the mucosa, can not be recognized by palpation, and may yield to non-surgical treatment; but an ulcer that includes the peritoneal coat can be felt during operation and is always a surgical lesion.

Seventh: When, governed by these thoughts, we have made a painstaking investigation of a patient suffering from an obscure stomach trouble and have weighed the history and each symptom carefully and are still in doubt, we should consider the advisability of applying the crucial test, viz., making an exploratory incision. We are all prone to postpone this operation, but with the assurance of perfect safety our improved technic gives, and the dangers of a delayed diagnosis in mind, I feel sure that it should always be done when in doubt, and the preponderance of evidence indicates the probability of ulcer. To wait for the appearance of obstructive symptoms, perforation, hemorrhage, tumor, or involvement of nearby structures to confirm a strong suspicion of ulcer would mean that we contend with a resultant pathology in every instance, and is nearly equivalent to waiting for abscess formation before operating for appendicitis.

Our new symptomatology of gastric ulcer is only just beginning to be formed; but we who essay to do surgery may know that when it is perfected it will be based on a clearer mental picture of the antecedent existing and resultant pathology drawn not alone from dead house findings and laboratory researches, but from observations on living subjects in our operating rooms.

THE M'GRAW LIGATURE.*

A. J. OCHSNER, B.S., F.R.M.S., M.D.
Surgeon-in-Chief of Augustana Hospital and St. Mary's Hospital;
Professor of Clinical Surgery in the Medical Department
of the University of Illinois.
CHICAGO.

More than fifteen years ago, Theodore A. McGraw invented a method of intestinal anastomosis by means of an elastic ligature. As chairman of the Section on Surgery and Anatomy of this Association, he described this method in his address and it was published in The Journal of the American Medical Association May 16, 1891.

The method was tried by its author in a large number of experiments on dogs and twice on human beings before this report was made. He then abandoned the method and employed in its place the Murphy button, which was introduced in 1892.

It was not until 1900 that McGraw again brought his method prominently before the medical profession in a paper read before the Mississippi Valley Medical Society[1] at Put-in-Bay.

Singularly enough, I listened to the papers at both of *these meetings*, but did not have the courage to employ this method of anastomosis until December, 1902, after seeing McGraw demonstrate his plan on the dog.

It seemed to be a thoroughly reasonable method, but it seemed to involve more risk than was proper without having seen the actual application of the various steps as they had been developed experimentally by the author.

He had demonstrated for me the various steps on artificially prepared organs, but the impression was quite different from that obtained when the operation was performed on the living animal.

After seeing the operation, I was convinced that its application was justifiable.

Since that time I have used the method 156 times and I have come to the following conclusions:

1. Anastomosis with the McGraw elastic ligature can be accomplished in a satisfactory way (a) between stomach and intestines, (b) between intestine and intestine.
2. The opening can be made any desired length.
3. It can be made without carrying infectious material from the lining of the stomach or intestine to the peritoneum.
4. It can be performed quickly.
5. It requires no special skill or ingenuity.

Clinical Experience With McGraw Ligature.

No.	Age.	Sex.	Occupation.	Admission.	Discharge.	Diagnosis.	Complications.	Treatment.	Remarks.
1	39	F	House wife.	1/7/03	2/1/03	Carcinoma of stomach.......	None..	Gastroenterostomy, McGraw ligature.	Carcinoma involving entire posterior wall of stomach.
2	49	M	Piano key maker.	1/27/03	2/11/03	Carcinoma of stomach.......	Tumor invol'd retroperitoneal glands.	Gastroenterostomy, McGraw ligature.	Carcinoma involving posterior wall of stomach and retroperitoneal glands
3	37	M	Farmer.	2/1/03	3/1/03	Pyloric obstruction, ulcer, dilated stomach.	None..........	Gastroenterostomy, McGraw ligature.	Ulcer 3 c. m. in diameter at pylorus.
4	30	F	House wife.	2/2/03	2/25/03	Pyloric obstruction, non-maglignant.	None..........	Gastroenterostomy, McGraw ligature.	Cicatricial contraction of pylorus.
5	57	M	Railr'd man.	2/14/03	3/12/03	Chronic appendicitis, pyloric obstruction, (cicatricial ?)	Chronic appendicitis.	Gastroenterostomy, McGraw ligature; excised appendix.	Large indurated mass about pylorus, apparently cicatricial.
6	30	F	House work.	2/21/03	3/29/03	Pyloric obstruction from ulcer.	None..........	Gastroenterostomy, McGraw ligature.	Some induration of pylorus with enlargement of glands about.
7	45	M	Coal miner.	3/24/03	4/7/03	Chronic appendicitis, carcinoma of stomach, adherent gall bladder.	Chronic appendicitis.	Gastroenterostomy, McGraw ligature.	Large carcinomatous mass near pylorus.
8	55	F	House work.	3/29/03	4/27/03	Right femoral hernia, right ovarian cyst, carcinoma of stomach, gallstones.	Gallstones.....	Gastroenterostomy, McGraw ligature; removal of fifty gallstones; herniotomy.	Carcinoma of pylorus with glands extensively involved.
9	32	F	House work.	4/5/03	5/2/03	Pyloric obstruction..........	None..........	Excised pylorus; enlarged old gastroenterostomy opening by means of McGraw ligature.	Had gastroenterostromy by means of Murphy botton 8 months previously for cicatricial stenosis.
10	65	F	House wife.	4/10/03	5/7/03	Gallstones, pyloric obstruction, chronic pancreatitis.	Gallstones and chronic pancreatitis.	Gastroenterostomy, McGraw ligature; 27 gallstones removed.	Marked hypertrophy of tissue about pylorus with obstruction.
11	29	F	Laundry girl.	4/26/03	6/18/03	Chronic appendicitis, dilated stomach.	Chronic appendicitis.	Finney's operation by means of McGraw ligature.	Found gastroptosis.
12	33	F	House wife.	5/9/03	5/28/02	Chronic appendicitis, pyloric obstruction, cicatricial: general enteroptosis.	Chronic appendicitis.	Gastroenterostomy, McGraw ligature.	Cicatricial stenosis of pylorus and general enteroptosis.
13	27	M	Piano finis'r.	5/26/03	8/2/03	Cicatricial constriction of pylorus.	None	Finney's operation by means of McGraw ligature.	Found cicatricial contraction of pylorus; no relief of symptoms for six weeks.
14	33	M	Coachman.	5/27/03	7/15/03	Non-malignant stricture of pylorus.	None..........	Gastroenterostomy, McGraw ligature; closure of pylorus by placing silver wire around.	Cicatricial contraction of pylorus, greatly dilated stomach.
15	53	M	Farmer.	6/1/03	6/20/03	Carcinoma of stomach, pyloric obstruction.	None..........	Gastroenterostomy, McGraw ligature.	No vomiting, but patient has had daily gastric lavage for four months.
16	34	F	Cook ..	6/1/03	6/27/03	Pyloric obstruction from old ulcer.	None....	Gastroenterostomy, McGraw ligature; closed pylorus by passing silver wire around.	Cicatricial stenosis of pylorus.
17	44	F	House wife.	6/2/03	7/2/03	Dilated stomach, pyloric obstruction, non-maligant.	Cholecystitis..	Gastroenterostomy, McGraw ligature.	Pylorus small; stomach greatly dilated.
18	25	F	House wife.	6/10/03	7/5/03	Ulcer of stomach, pyloric obstruction.	None......	Gastroenterestomy, McGraw ligature.	Small ulcer of pylorus; large scar on lower border near pylorus.
19	40	F	House wife.	6/16/03	7/18/03	Ulcer of stomach, pyloric obstruction, ovarian cyst.	Ovarian cyst .	Gastroenterostomy, McGraw ligature; excised right ovary and tube.	Large ulcer posteriorly, near pylorus.
20	36	F	House wife.	6/16/03	7/10/03	Carcinoma of stomach.	None	Gastroenterostomy, McGraw ligture.	Carcinoma of pylorus with complete obstruction; extensive enlargement of glands.
21	41	M	Farmer.	6/27/03	8/7/03	Carcimona of stomach, chronic appendicitis.	Chronic appendicitis.	Excision of appendix, gastroenterostomy, McGraw ligature.	Carcinoma involving pylorus and pancreas. Patient did fairly well for 3 weeks, then gradually became weaker and died 6 weeks after operation.
22	16	F	School girl.	6/28/03	7/22/03	Gastric ulcer...............	None	Gastroenterostomy, McGraw ligature.	Had operation for appendicitis one year previously; ulcer on inferior surface pylorus.
23	21	F	House-work.	7/1/03	10/22/03	Gastric ulcer.................	None	Gastroenterostomy, McGraw ligature.	Ulcer of posterior wall near pylorus.
24	44	M	Farmer.	7/4/03	7/24/03	Carcinoma of stomach.......	None	Gastroenterostomy, McGraw ligature.	Carcinoma posterior wall; extensive glandular involvement.
25	33	F	House wife.	7/11/03	9/21/03	Gastric ulcer, pyloric obstruction, peritoneal adhesions.	Cholecystitis..	Gastroenterostomy, McGraw ligture; drained gall bladder.	A round ulcer on posterior wall of stomach.
26	28	M	Janitor	7/14/03	8/23/03	Gastric ulcer...............	None	Gastroenterostomy, McGraw ligature.	Small ulcer near pylorus.
27	19	F	Laundress.	7/15/03	8/10/03	Gastric ulcer, pyloric obstruction, adherent gall bladder.	Chronic appendicitis.	Gastroenterostomy, McGraw ligature.	Pylorus adherent to gall bladder. Two large scars, one at pylorus, one on posterior wall of stomach.
28	27	M	Switchman.	7/16/03	8/9/03	Chronic appendicitis, pyloric obstruction, old ulcer.	Chronic appendicitis.	Gastroenterostomy, McGraw ligature; excised appendix.	A scar at pylorus; greatly dilated stomach.
29	48	M	Farmer.	7/29/03	8/23/03	Dilated stomach, cholecystitis.	Cholecystitis..	Gastroenterostomy, McGraw lig-	Cicatricial stenosis of pylorus; greatly dilated stomach.
30	38	M	Farming engineer.	8/4/03	9/5/03	Carcinoma of stomach.......	None......	[illegible] g- ature.	Stomach had two distinct, separate carcinomatous growths, one on anterior and one on posterior wall.
31	44	F	House-wife.	8/13/03	9/20/03	Dilated stomach, varicose veins, hemorrhoids.	Hemorrhoids and varicose veins.	Gastroenterostomy, McGraw ligature.	Had appendix removed 2 years previously; numerous adhesions about pylorus.
32	61	M	Merchant.	8/23/03	9/14/03	Gastric ulcer, stenosis of pylorus, cholecystitis, pancreatitis, appendicitis obliterans, right inguinal hernia, hypertr'y of prostate gland	Cholecystitis pancreatitis chronic appendicitis.	Cholecystostomy, gastroenterostomy, McGraw ligature; excision of appendix.	Greatly dilated stomach; ulcer with marked stenosis; also had cystitis; died three weeks after operation.
33	33	F	House-wife.	8/30/03	10/1/03	Gastric ulcer, chronic appendicitis.	Chronic appen[illegible]	Gastroenterost[illegible] McGraw lig- [illegible] appendix.	Ulcer on anterior wall.
34	65	F	House-wife.	9/9/03	9/24/03	Carcinoma of stomach, pyloric obstruction.	None	[illegible] McGraw ligature.	Large carcinoma with complete obstruction; greatly emaciated; died 15 days after operation from exhaustion.
35	38	F	House-wife.	9/10/03	10/18/03	Gastric ulcer, chronic appendicitis, tubercular salpingitis duplex.	Chronic appendicitis, tuberculous salpingitis.	Gastroenterostomy, McGraw ligature; excision of both tubes, ovaries and appendix.	Ulcer on posterior wall of pylorus; both ovaries and tubes and uterus covered with tubercles.
36	43	M	Janitor	[illegible]	[illegible]	[illegible] c appen- [illegible] left; hydrocele, right.	Chronic appendicitis.	Gastroenterostomy, McGraw ligature, excision of appendix; excision of varicocele, inversion tunica vaginalis.	Ulcer size of twenty-five cent piece on anterior wall.
37	47	F	House-wife.	9/28/03	11/4/03	Carcinoma of stomach........	None....	Gastroenterostomy, McGraw ligature.	Large carcinoma on anterior wall near pylorus involving pancreas.
38	42	M	Farmer	10/13/03	11/3/03	Pyloric obstruction.	None.........	Gastroenterostomy, McGraw ligature.	A hard cicatricial ring about pylorus.
39	28	F	None...	10/13/03	11/16/03	Gastric ulcer and chronic appendicitis.	Chronic appendicitis.	Gastroenterostomy, McGraw ligature; appendix removed.	Ulcer size of a nickel on anterior wall near pylorus.
40	40	M	Farmer.	10/14/03	11/25/03	Ulcer of stomach (?) Carcinoma.	None..	Gastroenterostomy, McGraw ligature.	A thickened area in lesser curvature of stomach: impossible to say whether ulcer or malignant.

Clinical Experience With McGraw Ligature.—Continued.

No.	Age.	Sex.	Occupation.	Admission.	Discharge.	Diagnosis.	Complication.	Treatment.	Remarks.
41	50	M	Farmer.	10/28/03	11/30/03	Ulcer of stomach, cholecystitis.	Cholecystitis..	Gastroenterostomy, McGraw ligature; drained gall bladder.	Ulcer on posterior wall near pylorus.
42	32	F	House-wife.	11/10/03	12/21/03	Contracted gastroenterostomy opening, intestinal adhesions.	Intestinal adhesions.	Enlarged old gastro[illegible] opening by means [illegible] ligature.	[illegible] oenterostomy opening made [illegible] months ago; enlarged by McGraw ligature seven months ago.
43	39	M	Cabn't-maker.	12/6/03	1/19/04	Appendicitis, carcimona of pylorus.	Chronic appendicitis.	Gastroenterostomy, McGraw ligature; excised appendix.	Indurated area on posterior wall of stomach near pylorus; question as to malignancy.
44	59	F	House-wife.	1/2/04	1/4/04	Carcimona of stomach, obstruction of pylorus.	Gallstones.. ..	Gastroenterostomy, McGraw ligature.	Carcinoma involving pancreas; complete obstruction of pylorus; greatly emaciated; died from shock, 2d day.

6. The patient shows very little, if any, shock after the operation.

7. The patients are relatively very free from pain and can usually sit up in bed with the aid of a head-rest a few hours after the operation.

8. The method should not be employed in making a pyloroplasty.

9. It should not be used in making a cholecystenterostomy.

I will here add four conclusions from Dr. McGraw's paper which will undoubtedly be of great value to those who do not possess his original paper.

1. The ligature should not be a rubber thread nor a flat band; these lack the necessary strength to cut their way with certainty through the thick walls of the stomach. The surgeon must use a hard, round, smooth and strong rubber cord, at least 2 millimeters in diameter.

2. It must include in one loop all the tissue which it is desirable to sever. The formation of small connected loops is an error. In general, the larger the amount of tissue included in the loop the quicker and more certainly will the ligature perform its work.

3. The cord must be drawn as firmly and tightly together as possible and fastened by a silk thread, which is tied around it. I have myself tied the rubber first in a single knot, fastened the silk around it, and then repeated the process for the sake of greater security. This may not be necessary, as the knotting of the silk thread once would probably serve the purpose.

4. Before inserting the rubber ligature the viscera should be joined together by a row of Lembert sutures for a distance of six or seven centimeters, and when the ligature has been tied a similar row in the front should complete the function. If ever there should be an ill success with the ligature, it will, I believe, occur from its too rapid action. The failures to cut through observed by certain German surgeons have, as I said before, been due to some fault in the technic.

I have formulated the method in ten short, concise steps which can easily be followed, especially when one has seen the beautiful drawings which Dr. H. O. Walker published in The Journal of the American Medical Association Jan. 17, 1903, page 166.

1. A round rubber cord, 2 mm. in diameter, made of the best material, should be used.

2. A posterior row of Lembert sutures is applied.

3. A long straight needle, armed with the rubber ligature is passed into the lumen of the intestine and out again at the desired distance, from 5 to 10 cm. away from the point of introduction.

4. While an assistant holds the intestine the surgeon stretches the rubber in the needle, and when quite thin draws it rapidly through the intestine.

5. The same step is repeated through the stomach.

6. A strong silk ligature is placed across and underneath the rubber ligature between the latter and the point where the stomach and the intestine come together.

7. A single tie is made in the rubber ligature after the latter has been drawn very tightly.

8. The silk ligature is passed around the ends of the rubber ligature where they cross, and tied securely three times.

9. The ends of the latter are released and cut off, being held by the silk ligature.

10. The Lembert suture is continued around in front until the point of its beginning is reached, where it will be tied.

11. Care must be exercised to prevent tying the rubber ligature too far backward and thus getting behind the posterior row of Lembert sutures.

I have used the McGraw elastic ligature 156 times. All but 32 of these operations were performed at the Augustana Hospital. I have had the 124 cases in which the patients were operated on in this institution carefully tabulated in order to give as comprehensive an idea as possible in the smallest amount of space.

Of these cases, 28 patients were operated on for the relief of pyloric obstruction due to the presence of a malignant growth. Of this group 5 patients died. All of these were greatly reduced by their disease and they all died of exhaustion.

Ninety-six patients were operated on for the relief of conditions due to non-malignant disease. In all of these cases, there was obstruction to the pylorus due either to cicatricial contraction resulting from ulcer or to the presence of an acute or a chronic ulcer.

In this series of 96 cases, there were five deaths. In Case 32 in the table, the patient was 64 years of age and very much reduced. He suffered from chronic appendicitis, cholecystitis with pancreatitis and ulcer of the pylorus with obstruction, and with a greatly dilated stomach. He also suffered from right inguinal hernia, hypertrophy of the prostate and cystitis.

I removed the appendix, made a cholecystostomy, and found a great quantity of thick, black, sandy bile in the gall bladder, which accounted for the pancreatitis. I also made a gastroenterostomy with the McGraw ligature. The patient died three weeks after the operation from exhaustion.

Had better surgical judgment been used, it is possible that this patient might have recovered. He was too greatly reduced to bear the extensive operation at his age.

It would have been proper to remove the appendix and to have made a cholecystostomy at the first operation, to have used gastric lavage and concentrated food by mouth and rectal feeding for a time, to have made the gastroenterostomy and herniotomy at a second operation and a perineal prostatectomy at a third, unless the continued rest in bed had in the meantime relieved the condition of the prostate at least for a time, thus postponing the indication for its removal temporarily.

In Case 55 in the table, a woman, 58 years of age, had previously been operated on. A gastroenterostomy opening which had been made two years before with the Murphy button had contracted until it was just large enough to admit a uterine probe. This was enlarged by the use of a McGraw ligature, and a second ligature was employed to make an opening between the two branches of the jejunum. A cholecystostomy was made and a gallstone removed.

The patient was a mere skeleton when operated on. She died on the ninth day from exhaustion.

It is doubtful whether this patient's life could have been saved by any method.

In Case 94, a man, 64 years old, had pyloric obstruction resulting in gastric dilatation and marked malnutrition. He died from starvation three weeks after the operation; no autopsy was permitted, and we were unable to determine why the patient could not assimilate the food he was given.

In Case 104 of this series the patient died of shock. He was 49 years of age, and the same error in judgment was committed as in Case 32, with a more immediately fatal result.

Case 107 in this series was more instructive, because it explained a condition which I had met before after gastroenterostomy, but which I had been unable to explain.

The patient, a woman, aged 34, suffered from an ulcer of the duodenum, with a greatly distended stomach. She also had a movable right kidney and a lacerated perineum. I made a gastroenterostomy with the McGraw ligature and an enteroenterostomy of the jejunum with needle and thread. A perineorrhaphy was also done. The patient did very well until the fourth day, when she suddenly complained of difficulty in respiration. She died within a few hours. The patient had been in the sitting posture, and we had not diagnosed the cause of her death. An autopsy showed an enormous dilatation of the stomach. The abdominal bandage had made it impossible for the abdominal wall to dilate; hence, the diaphragm had been pushed upward, the heart had suddenly been pushed out of its place, which accounted for the dyspnea and the sudden death. Had a stomach tube been inserted and gastric lavage employed, this patient would have recovered, as she was in an excellent condition before this accident occurred.

I will not compare this with other methods, but will simply record these clinical facts in support of the conclusions made at the beginning of this paper.

DISCUSSION

ON PAPERS OF DRS. MAYO, NILES AND OCHSNER.

Dr. Hugo O. Pantzer, Indianapolis, said that in a certain percentage of cases it is possible to palpate an ulcer accompanied with induration, and that tenderness, increased consistency and tumefaction should be painstakingly searched for. He reported briefly a case of anterior implantation of the duodenum into the stomach for stenosis of the pylorus, in which the patient suffered extreme gastrectasis owing to the almost complete occlusion of the pylorus. The duodenum was dissevered, the pyloric end of the stomach closed with running suture, and the duodenum implanted into the stomach just proximal to the thickened, ulcerated pylorus. The patient at the time of the operation was *in extremis*. Dr. Pantzer saw the patient three months before the operation and at that time he found a tumor of the pylorus the size of a goose egg, the stomach filling practically the entire abdomen. Operation at that time was refused. Just before the operation the local conditions were practically the same. The patient was extremely emaciated and enfeebled, necessitating quick work. A slit transverse to the circular fibers of the pylorus of length equal to the outstretched duodenal opening was made, the ends of which, together with the angle of the transverse incision in the stomach, were caught up by two guy-rope sutures; then a running suture, a continuous suture all around and one or two enforcing sutures where the knot of the former was placed, completed the anastomosis. The patient made an uneventful recovery. On the third day feeding by stomach was resumed. At no time was there the least evidence of defective drainage. The patient recovered good health quickly and fully. For over twenty years she had had stomach trouble and was restricted to a limited diet; since the operation she eats all kinds of food without any difficulty. The operation here practiced is virtually the implantation of the duodenum into the stomach, as done by Billroth after pylorectomy for cancer. Examination of Dr. Pantzer's patient six months after operation, and again recently, fails to reveal any tumefaction in the region of the pylorus. The patient was presented before the Marion County Medical Society and examined by several surgeons. It is fair to suppose that restitution occurs here as elsewhere in the body. When the source of irritation, the flow of acid gastric contents over the ulcerated areas, ceases, it is reasonable to expect a cure of the ulcer and subsidence of the inflammatory swelling. On this supposition it is not necessary to remove the thickened pylorus in ulcer cases, as has been advocated by Rodman. Dr. Pantzer expressed his conviction that several rows of sutures in intestinal surgery are often the cause of bad functional results. A single peritoneal suture correctly and carefully placed, with here and there an enforcing suture, usually will be found all-sufficient. The immediate drainage provided by this method will obviate the bad effects resulting from methods wherein the opening between stomach and intestine is delayed, as when the McGraw elastic ligature is employed. An opening provided, as in Dr. Pantzer's case, will continue patent. Experience has shown that the patency of gastrointestinal openings is less assured, particularly in cases in which the pylorus remains. The extent to which this operation is available, and to what extent it may take the place of the more complicated procedures, must be ascertained by further experience.

Dr. A. P. Francine, Philadelphia, read a brief extract of the statistics to which Dr. Mayo referred. They were obtained from the analysis of 2,830 consecutive autopsies in the Philadelphia Hospital. In this number there were 42 cases of ulcer, of which 2 were purely duodenal. He analyzed the associated condition or disease in these cases and found that in 17 there was chronic nephritis; in 12 tuberculosis, either miliary or of the lungs; and in 3 both tuberculosis and nephritis. Thus in 76 per cent. of the cases there was an associated condition of either nephritis or tuberculosis, and it would be interesting to know what relation, if any, these diseases bear to the gastric ulcers. In 20 out of 42 cases, or 47 per cent., the ulcers were multiple. Mayo says that in 20 per cent. of cases more than one ulcer is present. Brinton, in 463 autopsies on patients with ulcer of the stomach, found 57 with two ulcers, 16 with three or four, 2 with five, and 4 with more than five. The sexes in this series were equally divided, there being 21 males and 21 females, and the average age for the males was 43 years and for the females the same, a remarkably equal distribution. Welch, in his statistics, found 40 per cent. in males and 60 per cent. in females. The largest number of cases in his series occurred in males between 30 and 40 years, and in females between 20 and 30 years, but there was much uniformity in the distribution in relation to the four decades. In Dr. Francine's series the greatest number of cases occurred in males between 50 and 60 years, and in females between 40 and 50 years. Here, too, there was a tolerable uniformity in relation to the four decades. Three of the cases were in infants, aged 10, 20 and 36 months respectively. Osler mentions a case reported by Godhart in an infant 30 hours old. It should be borne in mind in relation to these figures that the age given is the age of death, not the age of the incidence of the ulcer, which must be considered as occurring earlier. In regard to size, Osler mentions an ulcer 19 cm. by 10 cm., reported by Peabody, as the largest one he knows of. The largest one in Dr. Francine's series was 9 cm. to 10 cm. by 8 cm. to 10 cm. Osler also refers to a case reported by Berthold in which there were 34 small ulcers. Similar cases of multiple ulcers are seen in some of Dr. Francine's cases. The total number of medical admissions to the Philadelphia Hospital for ten years from Jan. 1, 1893, to Dec. 31, 1902, inclusive, was 39,542. The total number of autopsies was 2,830. The total number of ulcers was 42, of which two were purely duodenal. The summary, therefore, including the figures given by Dr. Howard for the Pennsylvania and University hospitals, is as follows:

Hospitals.	No. of Autopsies.	No. of Gastric Ulcers.	Percentage.
Philadelphia Hospital	2,830	40	1.41
Pennsylvania Hospital	547	7	1.28
University Hospital	279	3	1.07
Phipps Institute	107	1	0.94
City of Philadelphia	3,763	51	1.32

Dr. George Goodhue, Dayton, Ohio, acknowledged the quickness with which the McGraw ligatures are applied and the fact that the opening does not contract, but he does not see that the ligature has any great advantage over the old procedure. On the other hand, there are disadvantages, the principal one being that it interferes with early nutrition through the stomach. It takes three or four days for this ligature to cut through, so that nothing can pass from the stomach to the intestines,and during this time nutrition from the stomach can not be secured. In many cases early nutrition is important, and Dr. Goodhue thinks this is the great objection to the McGraw ligature.

Dr. J. H. Carstens, Detroit, Mich., said that an operation can not be described; it must be seen. If a physician simply reads the description of a written article he will probably make a little break and discard it, but if he would go to the surgeon and see him do it he would have no trouble. Dr. Ochsner says the operation is not good for pyloroplasty, but it seems to Dr. Carstens that it is in just such cases that it does good.

Dr. Andrew C. Smith, Portland, Ore., said that Finney's operation as Finney performs it is an ideal procedure in all cases of benign stenosis. As Moynihan's modification of gastroenterostomy has no loop, it is a much less complicated operation. Dr. Smith's experience, though limited to three cases, sustains Moynihan's assertion that it does not cause vicious circle.

Dr. A. J. Ochsner, Chicago, stated that reasoning *a priori* he had come to the same conclusions as Dr. Carstens. Dr. Ochsner saw Dr. Finney demonstrate his operation, and it seemed to him as though that operation performed with the McGraw ligature would be an ideal operation. Dr. Ochsner performed it in three cases, and all of them were unsatisfactory. It is possible that he simply chose three unfavorable cases, and it is equally possible that in each case the Finney operation would have resulted badly. The operation looked very beautiful after it was completed, and when he had finished the first one he felt certain that it would be an operation he should constantly use. Dr. Ochsner believes that there is some reason for fearing interference with the early nutrition through the stomach. With the Moynihan operation, and the one which Dr. Mayo makes at the present time, the patient can be fed at once. With this method if the patients are very weak and the pylorus is not entirely occluded, Dr. Ochsner has fed them within twenty-four hours. They have not been quite so well as the others, and that is an objection. There is not a communication that is sufficient, unless there is a partly open pylorus. Dr. Ochsner has done the operation described by Dr. Pantzer, using the McGraw ligature for making the anastomosis. He irrigated the stomach thoroughly before the operation and communication occurred soon enough to be perfectly satisfactory.

Dr. W. J. Mayo, in reply to a question, said that the Finney operation is ideal when it can be properly carried out, but it took two deaths to teach him that one can not do the Finney operation safely if there be a large amount of scar tissue in the vicinity, and especially along the suture line. In suitable cases, it is the operation of choice. He called attention to one good feature of the method of gastrojejunostomy advocated; it is not only easy and safe of performance, but it gets the food into the jejunum at the highest possible point. Practically every operator in some way or other has had to make provision for possible biliary complications in all the loop operations. Dr. Mayo has done this no-loop operation about sixty times. In two cases there has been trouble with bile. A little would get into the stomach and make the patient very uncomfortable, but in spite of this these patients gain so much in strength and health that he has not as yet considered it wise to operate to relieve the condition. From previous experience with such complications, however, he presumes that a second operation may be required to produce a cure. The percentage of such complications will prove to be as small in this as in any of the simple suture operations. It is true that the Roux operation and some of its modifications are not open to this objection, but the operative manipulations are very extensive, take a longer time and have risks that are not found in the method described. The opening of the common duct, which lies four inches below the pylorus, really marks the beginning of the small intestine. In this operation food gets into the jejunum eight inches below this point. By getting the food into the intestine high up, a large amount of absorptive surface is saved, which is lost in all the loop operations. Dr. Mayo believes that some valuable changes in technic will overcome the few remaining difficulties which are not now of serious importance, as they can easily be corrected.

The Public and the Profession.—The public at large will hold no high estimate of those engaged in any calling if the members themselves do not stand up for each other. There is no place for jealousy in the heart of the true physician.—McCormack.

PERIODIC PARALYSIS.*

GEORGE E. HOLTZAPPLE, M.D.
Physician to York Hospital.
YORK, PA.

This very unique and rare affection has been recognized by various European and a few American observers. Dr. E. W. Taylor[1] of Boston, in a very extensive and carefully written article on this subject, gives, in chronological order, a complete bibliography of all the cases that had been previously reported in detail. Some of the cases reported in this summary do not have the characteristic features of family periodic paralysis, e. g., Cavaré, in 1853, described a case of general paralysis of the lower extremities. Both were quotidian in type and relieved by the administration of quinin. In 1882 V. P. Gibney reported the case of a child of 7, who after an attack of malaria suffered from paralysis of the four extremities. Recovery was slow. There is almost no similarity between these cases and those of typical periodic paralysis.

The first death was alluded to by Schachnowitsch in 1882, who described a case of intermittent paraplegia in a patient whose father was similarly affected and who is said to have died from increasing attacks. The first authentic case was reported by Westphal in 1885. It occurred in a boy of 12, beginning with a weakness and pricking sensation in his legs. Attacks usually came on at night. The patient would awake and find himself paralyzed. The muscles usually involved were those of the head, arms and legs. Those of the face, eyes, tongue and larynx remained free. The paralyzed muscles were flaccid. There was thirst, heat and sweating, and no excretion of urine. There were no mental nor sensory symptoms except tickling in the soles of the feet. Recovery usually occurred the following evening. Swallowing was usually unaffected. There was temporary enlargement of the heart, with murmurs indicative of cardiac insufficiency. Knee jerks were lost. At the height of an attack there was complete loss of electrical excitability. Later there was permanent weakness of the legs.

The number of cases reported in the summary by Taylor is 53. Thirty-five of these cases occurred in three families, which fact is sufficiently demonstrative that this is a distinctly hereditary affection.

Cousot reports 5, Goldflam 19 and Taylor 11 cases, respectively, having occurred in one family.

Three cases have since been reported by Drs. J. K. Mitchell, Flexner and Edsall. They found a diminished excretion of kreatinin for several days prior and at the onset of an attack, with a rise to the normal after the attacks.

It has been my privilege to live and practice for twenty-two years in the midst of a family suffering from this affection. In the cases thus far reported I have failed to learn of any deaths due to this disease, except one reported by Schachnowitsch, which classification was questioned by other observers, and I believe the disease is considered not serious. Osler says: "Improvement begins within a few hours or a day or two, the paralysis disappearing completely and the patient becoming perfectly well."

Of the family of which I write, six have died in an attack; one died in my presence. Many members of this family have suffered from attacks of periodic sick headache, which appears to be the equivalent to an attack of paralysis, both having a common cause, whatsoever that may be.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

[1] Journal of Mental and Nervous Diseases, September and October, 1898.

This affection in its typical form is characterized by periodic flaccid motor paralysis, involving all of the voluntary muscles, except those of the face, eyes, tongue, organs of speech, of deglutition and the sphincters of rectum and bladder. The attacks may be distinctly periodic for a time and at short intervals, especially in young adults, but frequently later in life at much longer and irregular intervals. The paralysis may be partial or complete, localized or general, the upper extremities alone or only the lower may be involved. It may be confined to the neck, or one-half of the body may be completely paralyzed, while partial paralysis affects the other half. The paralysis may be partial in the morning and become complete during the day.

During an attack of paralysis there may be one or more periods of marked improvement, usually of a few hours' duration, followed by complete helplessness. In a typical attack of complete general paralysis the patient is utterly helpless, can not move a finger or toe, can neither lift nor turn the head on the pillow, and if unsupported, the head either drops on the sternum or backward between the scapulas. In some instances breathing becomes distinctly labored, and deep breathing, cough and vomiting are impossible. Speech and deglutition are in rare instances affected. The order of involvement is not always the same. It most frequently begins in the muscles of the lower extremities, but may only involve those of the upper or the muscles of the neck. There are no sensory symptoms, except in some instances formication and numbness in the paralyzed parts, also a sense of heaviness and a tired feeling, which at times become very annoying to the patient, necessitating frequent change of posture, to the great relief of the patient.

During an attack of complete paralysis the reflexes and the faradic excitability are abolished in the paralyzed part, but return with the restoration of motor power. In some instances I have found the deep reflexes slightly exaggerated during the prodromal period, when the patient felt an impending attack, but I am not certain that this was the result of any change in the central nervous system caused by the approaching attack of paralysis. In such instances the reflexes were always abolished when the paralysis was complete.

Some can predict with a certainty an impending attack, others can not. If any symptoms precede an attack they consist of a peculiar heavy, tired feeling in the extremities, some numbness and formication, and some feel impelled to move and stretch themselves. These symptoms usually come on toward evening and may be accompanied by a voracious appetite, and if this is satiated by indulging in rich food, an attack is almost certain to be precipitated the following night. Over-indulgence in rich food is certain to result in an attack in some individuals, though at the time there may not have been an inordinate appetite; other members of this family are apparently unaffected by rich food, hard work and worry. Some will retire, feeling perfectly well, and awake to find themselves completely helpless, able to speak and swallow, but unable to move head, extremities or trunk. The onset is most always at night during sleep. When the individual wakes he may find himself partially paralyzed, possibly to become utterly helpless some hours later; or a period of marked improvement may be followed by complete paralysis. The onset may, therefore, be very abrupt, as in patients feeling perfectly well, retiring, and after sleeping a few hours, discover themselves helpless, or there may be premonitory symptoms during the preceding day. Some individuals may experience the heavy, sleepy, tired feeling, and sometimes a slight weakness in the extremities with an inco-ordination of the finer movements for days and in rare instances even a week, without the development of an attack. These are doubtless abortive attacks. The members of this family call this *"feeling the spell."* The duration of an attack may be a few hours, or one, two and in rare instances three full days. Improvement may be very rapid and of short duration, or it may require three or four hours, or even a half day. Improvement is sometimes interrupted by a recurrence of complete paralysis. This is not frequent. It is nothing uncommon for one of these patients to be as helpless as a log at 7 a. m. and at 11 a .m. be engaged in doing a hard day's work, not feeling the slightest inconvenience from having been completely paralyzed a few hours before.

In some, improvement is more rapid when it begins in the upper extremities and in others when it begins in the lower. The first symptom of improvement is simply the ability to produce slight muscular contraction here or there, may be a finger or toe, and this condition soon followed by the ability to move a large portion of the part involved.

Vomiting or one or two loose movements of the bowels sometimes occurs during the period of improvement. Some patients contend that forced exertion aids materially in hastening improvement or in warding off an impending attack. Some complain of muscular soreness on the day following attack, especially if they had to be handled much, while others do not complain of anything. The frequency of the attacks varies greatly in the different members of the family, and also in the same individual at different periods of life. They are usually most frequent between puberty and the middle period of life, and later become less frequent and more irregular.

Some members may be incapacitated for a few hours in the morning, daily, or once or twice a week, and in others the attacks may be at intervals of one or a few months and even longer. During last year it was a rare opportunity to see a typical attack of complete paralysis among the remaining ten members of this family who are subject to these attacks. During an attack there are absolutely no psychic symptoms. The mind remains perfectly clear, and in a patient who died in my presence it was clear until the last moment. The cranial nerves are not involved; none of the special senses have been affected. The bowels almost never move and urine is seldom voided during an attack, unless the bladder is overdistended. The patient retains full control of the sphincters of rectum and bladder.

Patients during an attack usually have no desire for food, some suffer slight nausea, but they usually take nothing but water, until they have fully recovered. In an ordinary attack the circulation remains good; the color of the lips and finger nails is normal and capillary circulation is not sluggish. During a very severe attack I have seen the pulse weak and irregular with evidence of cardiac dilatation. The temperature is not elevated. Some patients during a seizure are almost constantly affected by congestion of the conjunctivas and the mucous membranes of the respiratory tract. The accumulation of mucus in these cases may, at times, greatly embarrass breathing. It would be a serious misfortune for such to be taken with an attack in the midst of a severe cold.

Most of the members of this family began to have attacks at about the period of puberty or later in the second decade, and a few had seizures, at long intervals, as early as the eighth or ninth year. During the intervals between attacks these people seem perfectly well. The hereditary nature of this affection is, I think, established, inasmuch as every one of the paralytic group had either a father or mother who was subject to seizures of paralysis or sick headache, or both.

The general clinical description of the attacks of headache in this family is very much the same as of ordinary hemicrania. Most of these members began to have attacks when only a few years old. The attacks in many recurred once a week with great regularity until after puberty, when the intervals were usually somewhat longer. One member had weekly attacks of sick headache during her whole lifetime; death occurred at 76. These attacks were seldom associated with any apparent disorder of the digestive organs. A number had attacks until the age of 20 or 30 years, when they were replaced by attacks of paralysis, and a number had both alternately. A severe attack of headache would in some individuals seem to protect for a short period against an attack of paralysis.

I have made these observations during the last twenty-two years in a family in four generations. The total number of this family who have had periodic paralysis is seventeen. Eighteen members have had sick headache. Five had attacks of paralysis and headache. Fourteen members have had attacks of paralysis only, and thirteen have had attacks of only headache. The total number afflicted with either paralysis or headache is thirty-two.

Of the seventeen who have had attacks of periodic paralysis, ten are yet living. One of the seven who are dead died from chronic nephritis. The remaining six died in an attack of paralysis, one in my presence. Fourteen of this paralytic group have been under my personal observation. The disease was transmitted through the father having had attacks of paralysis, in six instances, through the mother in four instances; through the father having had attacks of sick headache only, in four instances, through the mother having had attacks of sick headache only, in three instances. In nine instances the disease was transmitted through the father and in eight through the mother.

The parents of the first generation were F. and M. O., of German descent. Both parents were hearty and well, except Mr. O., who was afflicted with periodic sick headache. There is no neuropathic history obtainable. The first generation consisted of five males and five females. Three of the sons had attacks of paralysis, one attack of headache and one was unaffected. Of the daughters, four had sick headache, none had attacks of paralysis and one was unaffected. I will append brief histories of the paralytic group:

Case 1.—Mr. M. O. is a member of the first generation, the oldest member now living, aged 70 years. His family history and early personal history are negative. There is no luetic history in the whole family. He was of strictly temperate habits, but used tobacco rather freely. He spent his early youth in a store and later served an apprenticeship as bricklayer. His first attack occurred at 14. The paralysis always came on at night. To indulge in rich food, especially in the evening, was sure to precipitate an attack, and to have a severe cold would predispose to a spell. There were no premonitory symptoms; he would retire feeling perfectly well, wake up and find himself helpless. In a severe attack he would be unable to move a finger or toe, neither could he take a deep breath and speech was often difficult. He could usually swallow well, and the muscles of the eyes and face were not involved, while the muscles of the neck were often completely paralyzed. He never suffered from headache and there were no mental symptoms. His appetite was usually gone, nausea was common, but he was never able to vomit. His bowels never moved during an attack, and he always had full control of the sphincters of the rectum and bladder. He never had pain in the extremities, even if handled by the nurse. *The paralyzed parts often felt numb.*

On examination he is found to be well nourished, color of skin, lips and mucous membrane is good. Tongue slightly coated, slight arcus senilis, arteries at wrist not very stiff. On examination, nothing of special interest is found except the muscles of the extremities are emaciated, and those of the lower so weak that locomotion is impossible. The extensor muscles of the extremities are all slightly stronger than the flexors. Tactile and painful sensations are normal above the hips. The weakness in the lower extremities began eighteen years ago and increased gradually until four years ago, when he was compelled to take an invalid chair. His arms are strong enough to work the chair. The special senses are unaffected, and there are no mental symptoms. The pupillary reflexes are normal. The tendon reflexes of the upper extremities are scarcely to be elicited and those of the lower extremities are abolished. The sphincters of the rectum and bladder are not affected.

Case 2.—C. F. O., son of Mr. O., had a very severe attack when 24. He died since from chronic nephritis. He left a son and daughter, thus far unaffected.

Case 3.—Mrs. J. G., daughter of M. O., now 32, has had repeated attacks since she was 15. The characteristic features of her attacks are almost identical to those which are found in the seizures of her father.

Case 4.—Mr. L. G., son of Mrs. J. G., a teacher, aged 18, had a number of typical attacks. As a child had measles and chicken pox. Never used alcohol, tobacco in moderation, coffee in small quantity. His appetite is good, bowels are regular, is regular with his meals, never indulges late at night, gets slight headache at long intervals, but never has the characteristic headache of this family.

Recently he had an attack which came on during the night. During the evening before he felt numb in his fingers and incordination for finer movements was very marked. The lower extremities were free from symptoms at this time. There was no headache, no gastric distress, no constipation. He was away from home, teaching, and without medicine. He retired at 10 p. m. At 2 a. m. he awoke and was paralyzed; could move only fingers and toes slightly. There were no sensory symptoms. Improvement began at noon, at 2 p. m. was able to sit up, and at 5 p. m. was able to walk with a cane, the following morning at 9 a. m. he had completely recovered. There was at this time some soreness in his legs. During the attack he had full control of his bladder and rectum; no urine was voided for twenty hours; no pain from distension. There was no gastric distress during attack or period of improvement, and the appetite was normal immediately after recovering completely. Later he had an attack, limited to his arms, at 6:30 a. m., when he took a dose of medicine. Sodii brom. ʒss. Caffein citras gr. ii, and at 9 a. m. had completely recovered.

Case 5.—Mr. J. O., member of the first generation, began to have attacks of periodic paralysis at the age of 20. He never had the characteristic headache. He was otherwise well, but the attacks of paralysis were of frequent occurrence until the age of 54, when he died in an attack.

Case 6.—Mr. J. O., Jr., began to have paralytic seizures at 16; they were often of weekly occurrence, frequently seen by me. The attacks were most severe during damp cold months. At the age of 25 he went to Missouri, had an attack and died.

Case 7.—Mrs. L. P., daughter of J. O., had attacks of headache until the age of 31, when the headache ceased, and she began to have attacks of periodic paralysis. The following is a description of a recent attack: She retired feeling well. At 1 a. m. she awoke, found herself helpless, except that she could move hands and feet. At 5 a. m. improvement commenced; at 9 a. m. it was complete. She cleaned a few rooms in her house, retired at 10 p. m., feeling perfectly well. Next morning at 4:30 she was again almost completely helpless. She improved some later on forced exertion, but at 12 noon she became worse again, and at 3 p. m. was completely paralyzed. I saw her at 6 p. m. She could move head from side to side, but could not lift it from the pillow, neither could she move a finger or toe. She suffered no pain when at rest, but on being handled, a rather severe, dull, muscular soreness. There was no numbness in the extremities; there were no mental symptoms; special senses and cranial nerves not involved. Speech and swallowing were unaffected. Color of skin, lips and mucous membrane normal. Pupils reacted readily to light and shade. Capillary circulation active. Temperature was normal, respiration 20, pulse 80, full, regular in force and rhythm, of good volume, tension normal. Her appetite was good, but she was afraid to eat. There was no nausea. She drank water freely and without difficulty. The bowels had not moved and urine was not voided since she was completely paralyzed; yet she felt that she had full control of the sphincters of the rectum and bladder. Breathing was sometimes a little labored and deep breathing was impossible. Heart sounds were clear, cardiac impulse easily felt, apex in fifth interspace in nipple line. Tactile and painful sensation normal. The tendon reflexes and the faradic excitability of the muscles involved were lost. I saw her the following day at 10.30 a. m. and found she had completely recovered. Her appetite was good, pulse 76, respiration 20. The tendon reflexes and faradic excitability were restored to normal. At 6.45 the preceding evening, as was her custom in such a condition, she took a dose of her medicine, sodii brom. ʒss. and caffein citras gr. i. At 7:30 she felt decided improvement. At 8 p. m. she took another dose; improvement continued, and at midnight she discovered herself well.

Case 8.—C. O., a member of the first generation, had frequent attacks of periodic paralysis during a period of three years when he died in an attack.

Case 9.—Mr. F. G., son of Mrs. J. G., later reported as having been afflicted with the characteristic headache, began to have attacks of periodic paralysis at 17. His family history is negative except for his mother's condition. His early history is negative, except that he had spasms when quite small. His attacks occurred at intervals of a week, to three of four months, most frequent in spring. The duration of an attack varied from a few hours to three full days. The attacks came on at night, and lack of exercise always predisposed to a seizure. He had attacks of headache more frequently than paralysis, and an attack of headache would protect him for a time against the development of an attack of paralysis.

He never suffered pain during an attack, nor muscular soreness afterward. He was a big eater, and attacks were always preceded by a voracious appetite, which, if satiated, was sure to precipitate an attack. He had no premonitions except the bulimia. During an attack his appetite was gone, bowels remained quiet, and he retained control of the sphincters of rectum and bladder. He was usually troubled by an accumulation of mucus in the throat and bronchial tubes, which at times greatly embarrassed his breathing. His mind always remained clear. His last attack developed during a Saturday night and continued unimproved until the following Monday at 9 a. m., when I was called to relieve him of the accumulation of mucus which had embarrassed his breathing very greatly. I found him cyanosed, breathing very much labored, pulse very irregular and at times imperceptible at the wrist, with the physical signs of cardiac dilatation. His mind was perfectly clear. I was with him until 9.30 a. m., when his pulse suddenly ceased to beat at the wrist. there was a vacant stare and he was dead. His age was 27.

Case 10.—Rev. E. O. G., a brother of the preceding patient, would sometimes have a tired and drowsy feeling toward evening that would betoken an impending attack. Sometimes an attack was preceded by slight jaundice. The onset was always at night. His attacks began at the age of 16, and recurred at intervals of a few days to a few months, being most frequent during damp cold months. During attacks he would suffer from a lame, tired feeling, which would necessitate frequent change of position. Improvement was sometimes abrupt, at other times it would require a few hours. He was often completely paralyzed in the morning, and in a few hours would be busily engaged in doing a hard day's work, not suffering any inconvenience from having been completely paralyzed just shortly before. His appetite and general health were usually good immediately after the return of the motor power. His last attack came on during a Saturday night and continued until the following Monday at 4 a. m. There was nothing unusual in the manifestations or behavior of this attack until at the hour mentioned he told his wife, who was nursing him, that he felt very badly, and expressed a wish to be turned on his side, which was done, when he requested to be quickly returned to his former position, and he was dead.

Case 11.—Mr. F. G., another brother of the preceding two, had repeated attacks at more or less irregular intervals. The characteristic features of his attacks were same as of all the rest. He was taken with colic, which continued for a week, when he was seized by an attack of paralysis, and died twenty-four hours later, at the age of 43.

Case 12.—Mrs. J. F., a sister of the preceding brothers, is still living and has attacks of headache and mild attacks of paralysis. It may be noted here that the three brothers above mentioned and this sister all had both headache and attacks of paralysis, and the disease was transmitted to them through their mother, who never had an attack of paralysis, but was a life-long sufferer from the characteristic headache.

Case 13.—Mrs. G. H., a daughter of Rev. E. O. G., is one of the most frequent sufferers now living. She is 24. There are times when she is incapacitated daily for a few hours in the morning, and at other times the intervals may be weeks or months. She gives positively no premonitory symptoms. Overeating, exertion and worry do not seem to predispose to an attack in her case. Attacks are more frequent in damp weather, and to lie in a draft at night is sure to precipitate an attack. When paralyzed she is simply helpless and has no pain anywhere. She may suffer some from sore throat and an accumulation of mucus. The paralysis may be partial or local, and appetite remains good. There is no nausea nor vomiting during the height of an attack, nor during the period of improvement, which was not uncommon in the case of her father. She does not seem to be affected by the kind or quantity of food taken. The following note was recently made which corresponds to repeated observations in her case:

She retired late in the evening, feeling perfectly well, except being slightly tired. During the night she awoke and was paralyzed. On examination, she complained of being little sore throughout her body. There were no sensory symptoms, no numbness, tingling nor formication. There was no muscular twitching; muscles of the neck and extremities were paralyzed; tactile and painful sensation normal; reflexes and faradic excitability in the affected parts were abolished. Pulse regular in force and rhythm, full, tension normal. Cardiac impulse strong, apex beat in nipple line, cardiac sounds clear, no murmurs. Pulmonic second not pathologically accentuated. Capillary circulation active. Respirations 21, not labored, but she was unable to take a deep breath. Temperature normal. Pupils reacted readily. She had little headache; eyes not sensitive to light. She had full control of the sphincters. An ordinary urinalysis and examination of blood negative.

Case 14.—Mr. H. F., the second son of Mrs. J. F., is one of the worst sufferers living. His family history is negative except that his mother has both the headache and paralysis. He gives no specific nor alcoholic history; had most of the diseases of childhood. He began to suffer from sick headache at 9. The attacks were frequent, but severe during damp seasons. At 16 he ceased to have headaches and began to have typical attacks of paralysis, some of which were very complete and protracted. His attacks are usually preceded by a tired, dull, irritable, sleepy feeling. There is usually some twitching of the muscles of the neck, trunk and extremities, besides a dry, stuffy feeling in the head; also a slight cough, injected conjunctivæ, and a numb feeling which gradually extends over the whole body. If he retires with these feelings he is sure to awake and find himself paralyzed. When the paralysis is incomplete the flexors are more affected than the extensors. The muscles of the face have at times been slightly involved. Swallowing and speech may be affected, and breathing is often labored, which is aggravated by the accumulation of mucus. Any gastric disorder is apt to be followed in his case by an attack of paralysis. He could bring on an attack at will by eating a rich meal in the evening. When an attack is about to come on he feels impelled to move and stretch himself, and this feeling is a frequent forerunner in his case.

Case 15.—G. F., daughter of H. F., aged 13 years; had the ordinary diseases of childhood, tonsillitis and complains of rheumatic pain in extremities. Had considerable headache last three years. Her first attack of paralysis occurred at 10; had attacks at long intervals since. So far she had no premonitory symptoms, goes to bed feeling well and awakes paralyzed. During an attack there is no nausea, nor pain; no headache, nor muscular soreness, but some soreness following an attack. If she wakes in the morning to find herself helpless, she has so far recovered by the following noon. Attacks have not been followed by any gastrointestinal disturbance.

Case 16.—Dr. F., a brother of H. F., has had a number of typical attacks, none the last few years. He is well built, a hearty man and enjoys splendid health.

Case 17.—Mrs. V. L., a sister to Dr. F. and H. F., aged 40, has only one daughter, aged 18, who has felt the attacks a number of times. No note is included in her case. Mrs. V. L. as a child had measles, mumps, chicken pox, later rheumatism and influenza. She lived an out-door life much of the time, and was well except for the disease named. She commenced to menstruate at 14, which has been regular since. No history of any disease or functional disturbance of any of the pelvic organs. She was always a hearty eater; bowels were regular and she never indulged in alcoholic drinks. Drinks freely of coffee, not much tea. Commenced to have attacks of headache at 15, which recurred every few months. Paralytic seizures set in at 22, and recurred as often as every week, sometimes every few months, and during rare intervals every day for a short period. On the day preceding an attack she would have a voracious appetite a tired, heavy, sleepy feeling in arms and legs, and usually more marked in the latter. When retiring with this feeling she would usually awake about midnight and find herself paralyzed. In a severe attack, and they were numerous, she would be unable to move a finger or toe, to turn or lift the head from pillow. She could swallow and speak, but breathing was often difficult, and coughing and sneezing would be impossible. Her attacks were never complicated by any catarrh of the respiratory tract. Appetite usually continued during an attack, though she avoided taking food, but would drink water. Never voided urine, and bowels never moved during the height of any attack. She had full control of the sphincters of the rectum and bladder. She suffered no pain except at times slight headache and a lame feeling in the extremities, which became painful unless their position was changed frequently. Paralysis would sometimes be limited to lower extremities, but never to neck or neck and upper extremities. There were no psychical symptoms, and special senses were not affected. Never had any cardiac distress during an attack. Duration was usually twelve to fifteen hours. Improvement usually started in the hands, and in one or two hours she would often have completely recovered. Patient thinks work and overeating predisposed to an attack, but not so by overexertion. Attacks were most frequent in fall and spring, and especially when it was damp. During period of improvement would often be nauseated, and have a few loose movements of the bowels. Paralytic attacks have been mild and very infrequent since she was 37. Her general condition at present is very good and suffers at times from slight rheumatic pain in the extremities.

I will here append a few histories, very briefly, of some of that suffer very severely from the characteristic headache:

Case 1.—Mrs. J. G., a member of the first generation, never had an attack of paralysis, but was the worst sufferer from sick headache in the four generations of this family. She had on an average one attack a week during her lifetime, each attack lasting about twenty-four hours. She seemed to be benefited by vomiting, but not by sleep. She was a moderate eater, though rich food did not seem to predispose to an attack. During an attack she was often chilly and nervous, but had no visionary disturbances. She never had any convulsive seizures, such as are sometimes seen in hemicrania. Thirst was an indication that improvement would soon set in. During the last three years of her life she became very weak and uncertain in her gait. At times she was almost completely helpless in her lower extremities; upper extremities were not appreciably affected. Sensation was much diminished in lower extremities. Mrs. J. G. had three sons and four daughters, and as noted before, all of the sons suffered from headache and paralysis, and all died in an attack of paralysis. Patient died at 76.

Case 2.—Mrs. I. S., a grand-daughter of Mrs. J. G., aged 38. During the interval between attacks she feels well. As a child she had measles, whooping cough, mumps and scarlet fever. Since this she was well and suffered only from headache, which attacks began when she was only a few years old. The attacks were most frequent and severe during the period of puberty and for a few years afterward, since which the intervals have been gradually becoming longer. When most frequent, attacks occurred once a week, now every few weeks. The attacks are nearly always preceded by vertigo gastric distress and inordinate appetite. Also by visionary disorders, such as floating specks and almost complete blindness. No swelling of the face during an attack. Vomiting often affords some relief. Recovery is slow and gradual, requiring from one to a few days. She is a good eater and has trouble with constipation. Physical examination during the interval between attacks is negative.

Case 3.—M. S., aged 13, a daughter of Mrs. I. S., when a small child had usual infantile diseases. Began to suffer with very characteristic attacks of sick headache when 2 years old. From the age of 5 to 12 years she had an average of one attack a week. At this time the attacks are further apart. She feels perfectly well between attacks, which usually come on during the night without any premonitory symptoms. Vomiting does not relieve her; she never has attacks of dyspnea or convulsive seizures during an attack. Her general condition is good, no icterus. Deep reflexes normal; physical examination negative.

Case 4.—Miss M. G., whose mother is a member of the first generation and a sufferer from headache, is a seamstress, aged 23. She is of small stature, well nourished, color good no jaundice. She feels well except for the attacks of headache, which began in early childhood. Always suffered much, but more severely last few years. Attacks vary in frequency of late, one attack every fortnight; vomiting is followed by some relief. She is a moderate eater, and regular with her meals. As a child, she had the common infantile diseases. At 18 she had rheumatism. She menstruates regularly and without pain. On physical examination nothing is found of any special significance except soft mitral systolic murmur transmitted to left midaxillary line, doubtless the result of a previous rheumatic endocarditis. There is also a systolic thrill in mitral area. Pulmonic second sound very slightly accentuated above the normal for a lady of 23. The radial at the wrist not palpable; liver and spleen not enlarged, neither tender on pressure.

I have thus attempted to give a brief sketch of the individuals of this family who have been afflicted with

TABLE OF URINALYSIS OF INDIVIDUALS SUBJECT TO ATTACKS OF PERIODIC PARALYSIS.

1. Mrs. L. P., age 51, weight 165 pounds.

this unique disease. I say disease, because some have been permanently crippled by it, and six have died in an attack, one in my presence; and whatsoever disorder causes permanent damage to the central nervous system, so as to cause a slow paralysis and very sudden death in over 35 per cent. of those affected, I think is worthy to be entitled a disease.

PATHOLOGY.

Numerous and very careful observations have been made, but we are yet ignorant of the pathology of this disease. The findings of a necropsy would doubtless reveal much that would explain the pathology, but no autopsy has thus far been obtainable in this family. Theories have been advanced, but none has been proved by demonstration. Some observers believe this condition is due to a toxemia affecting the nerve endings of the motor fibers in the muscles. Goldflam discovered vacuolation of some of the muscle fibers. Until the truth is positively known one dare have views of his own.

I have always been inclined to view this affection as a vasomotor neurosis affecting the blood supply to the anterior horns, which are supplied almost wholly by the anterior spinal artery. I do not know that vasomotor nerves have ever been demonstrated in the vessel walls of the spinal cord, but vasomotor centers do exist in the anterior horns, and it is not likely that the arteries supplying so important a tissue as is found in the anterior horns would not be supplied with vasomotor nerve-regulating influence. The nutritional changes noted in the muscle fibers may have been due to disturbance of function of the trophic cells. The exciting cause, be it toxic, may have a direct influence on the vasomotor nerves regulating the blood supply to this part of the central nervous system, or it may have an indirect influence, when due to gastrointestinal disturbance or when paralysis results from sleeping in a draft.

The slow but progressive permanent paralysis, which occurred late in life in two of the cases herein reported, I always believed to be due to a slow degeneration in the anterior horns, due to frequent disturbance of nutrition and the atrophy of the muscles due to involvement of the trophic cells. Only a careful autopsy will determine the validity of this argument. The paralysis in this disease always appeared to me to be closely allied to the paralysis which sometimes occurs in migraine or hemicrania, such as oculomotor paralysis, aphonia and paralysis of one extremity or of half of the body. Believing there is either a deficiency of elimination or the absorption of some toxic substance from the gastrointestinal tract, in either case resulting in an intoxication by some substance which may be the exciting cause of a supposed vasomotor spasm of the anterior spinal artery, thus causing temporary anemia and paralysis, and ultimately degeneration and permanent paralysis, I attempted some practical investigations to deter-

Average weight, 139.6 lbs.

mine if these people, as a class, differ in any way from those who are supposed to be perfectly well.

I obtained in all 139 specimens of urine, 73 specimens from six members of the paralytic group, 36 specimens from three individuals who have the characteristic headache, and 30 specimens from five persons who were the picture of health. From the patients I obtained a specimen of the mixed urine for twenty-four hours, on three successive days, at short intervals, and from the well, six specimens from each, on six successive days. The specimens were all submitted to the same examination and the results compared. The only findings recorded in these tables are the daily quantity voided, the specific gravity, the total quantity of urinary solids, the total quantity of urea and the presence of indican which is noted as marked, slight or absent. In none of these specimens was albumin found (only ordinary tests were used) nor sugar, though only those specimens were examined that had an abnormally high specific gravity. The significance of the presence of indican would serve as an index of the degree of putrefactive change of the foodstuff in the stomach and bowels, especially of the albuminoids. If regularly found in large quantity it would point to a possible source of intoxication. If either the total quantity of urinary solids or of urea are constantly below the normal, it would establish the existence of renal insufficiency and would point to an intoxication by the retention of one or more metabolic products, which may, in these people, having a peculiar idiosyncrasy, be the exciting cause of this mysterious affection. In comparing the accompanying tables we find the average quantity of urine voided, the average output of urinary solids, about normal in all the classes examined, i. e., the paralytic group, those subject to headache only, and the normal cases, but one is very much impressed at the marked diminution in the average quantity of urea eliminated by the members of the paralytic group. All of the individuals from whom these specimens were obtained live an active life, and, while the specimens were collected, none were subjected to any restrictions or change in their habits or mode of living.

There is also a striking daily variation in the quantity of urea eliminated by the members of the paralytic group, which is not in harmony with the variation in the quantity of urinary solids excreted. By excluding the little girl, aged 13, weight 75 pounds, from the paralytic group, it is seen that the worst sufferers are those in whom there is the most marked diminution in the average daily output of urea.

In the tables will be noted two specimens from H. F., examined after an attack, and two daily specimens following the one attack, yielding an average daily excretion of 100.7 grams of urinary solids and 24.9 grams urea, whereas the same individual excreted a daily average of 68.9 grams of urinary solids and 11.5 grams urea in twelve specimens examined between attacks. A summary of the average of all the observations made is as follows:

Individuals.	Average weight, lbs.	Average quantity, c. c.	Average solids grams.	Average urea grams.	Indican. Marked. Per ct.	Indican. Slight. Per ct.	Indican. Absent. Per ct.

In studying the accompanying tables every one can draw his own conclusions, but they seem to establish at least one fact, that the patients included in the paralytic group are not excreting the normal quantity of nitrogenous metabolic products. This being a family affection, there is doubtless a peculiar idiosyncrasy that makes these people susceptible to this peculiar affection when under the influence of some exciting cause, that would not so affect others. What relation there may be between this diminished excretion of urea and the paralysis, further observations may explain.

TREATMENT.

Believing that these attacks were due to a vasomotor spasm of the anterior spinal artery, I resolved to try large doses of bromid. I began this treatment twenty years ago, immediately after witnessing a death reported in this paper. The dose of bromid, preferably of potassium, usually consisted of ʒss with caffein citrate gr. i or ii, and this dose repeated in one or two hours. This seemed to give unmistakable relief, so that from this time on most of those who were subject to this disease kept the medicine on hand, and without exception, these patients were certain that while it did not cure, it did have a very decidedly abortive influence and hastened improvement, when taken during a paroxysm. Prior to this nothing was attempted but prophylactic measures when predisposing causes were known. Prophylaxis is an important matter with some, for if, in the presence of a severe acute catarrhal inflammation of the respiratory organs one should indulge in rich, heavy food, life might soon be in danger.

In one case reported, E. O. G. took one or two doses during the evening if he felt an impending attack, and for a period of two years he did not fail to meet a pulpit appointment. He was then taken with a febrile affection, which he attributed to the medicine taken, and from this time on he took no more bromid. During the two years he took the medicine he felt the attacks often. After the febrile attack, he was free from the disease for about a year. He was then taken with an attack on a Saturday evening, which continued until Monday at 4 a. m., when he died very suddenly. This was the first attack after he discontinued the bromid. He did not take the bromid unless he felt an impending attack, which he was always able to do. A number of these patients have told me that they feel an improvement invariably in half an hour after taking the medicine. I do not know of a single instance in which a severe attack developed when the bromid had been taken during the onset; small doses were never tried, only large doses to make a decided impression on the nervous system. The frequency of the attacks does not seem at all affected by the use of the bromid.

In these cases no autopsy has been obtainable, thus far, but the patient, aged 70, has consented to an autopsy after his death, and then we may learn more of the pathology of this disease.

AMERICAN HYGIENE.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON HYGIENE AND SANITARY SCIENCE, AT THE FIFTY-SIXTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, PORTLAND, ORE., JULY 11-14, 1905.

JOHN S. FULTON, M.D.
BALTIMORE.

The same Scripture which forbids a man to think of himself more highly than he ought to think, warns also against the opposite sin, bidding him think soberly, according as God has dealt to every man the measure of faith. Applying to the duty of this hour the rule and measure of scientific faith which has been dealt to me, I desire to consider soberly the office of this Section as a member, first, of the body medical, and afterward of that greater body in which the profession itself is a member—the body politic. If I confess no surprise that a majority of the members of the American Medical Association see in this Section no very distinguished merit, I imply no disparagement of the past history of the Section, nor any want of intelligence on the part of those who think less highly than I of the capabilities of this Section.

The Section on Hygiene and Sanitary Science seems to me in certain respects the most important division of the American Medical Association, and includes among its future possibilities a very eminent distinction, that of becoming the chosen agent in bringing the powerful and beneficent influence of medical common sense to bear on public opinion. That the Section will be raised to a place of such dignity and influence seems to me manifest destiny, and the question is not whether it shall come to pass, but when. Early—the answer is—if we recognize the advantage of our position and carry forward our responsibility; late—and to our disgrace—if the event must wait until the great body of the profession discovers the advantageous position of the Section on Hygiene and Sanitary Science. A mere perception that this Section articulates the medical profession to the body politic will not of itself commend us to the Association. It is interesting information, to be sure, but, stated in words it carries no conviction. Stated in works, the special utility of the Section will compel the interest of the Association and rapidly develop in the Section its true organic function.

A brief consideration of the circumstances which have been determined internal boundaries in the Association may help us to a better understanding of our own relations. The purpose of these annual meetings is primarily educational. Every man who speaks is for the time being a teacher; every man who listens is for the time being a learner. In the pursuit of information the members are free to go wherever their personal interest leads them, but one's desire to impart information is stringently regulated, first by the individual sense of power to contribute, and next by the selection which a man has made for the sake of a particular technical excellence. A man may gather honey or wax wherever he will, but he brings the product of his industry home to his own hive. Each division of the Association, therefore, stands toward the remainder of the Association as a source of knowledge, a teaching body; and, conversely, the Association as a whole is a student body, deriving from each of its subdivisions the particular knowledge on which the general efficiency of the profession is nourished.

The distinctions which separate the Association into sections are not equally sharp. Some of them cut so deep that, in order to be a highly efficient individual, one must practice within limits so definite and exclusive that he may lose in time many of the attributes and almost the name of a physician. Allowing for the influence of numbers, the most efficient divisions of the Association are made up of men whose names are but rarely in the mouths of the people, who are spoken of by us not as physicians, but as pathologists, anatomists or physiologists. These sections, in which the title of phyician is most apt to be abbreviated so that the special designation may be spelled out, are central to the body of medical science. About them are grouped other sections with looser distinctions, not wholly enclosed by the natural sciences, but having some contact with human affairs. The place of Section on Hygiene and Sanitary Science is peripheral to the body of medicine, and, in contrast with all the others, fully half of its area lies in political science. Here, more than anywhere else, "special knowledge will leak out, and general knowledge will leak in, though a profession were covered with twenty thicknesses of sheepskin diplomas." Here, or nowhere on medical territory, "statecraft and medical knowledge should sincerely take counsel together for the health of the people." From the reaction between American medicine and American politics, American hygiene results, and all its virtues are not derived from medicine, nor all its vices from politics.

The profession should be deeply concerned about the fate of its members who venture into this field. It is a rash adventure for any man, and the wonder is not that so many fail but that any succeed. All honor to those who in the past have done good work in American hygiene, and all charity for those who have been lost. Every one of them, whether surviving or perishing, came to his task in all but nakedness, for medical education does not prepare a man for the dangers of this field, nor is it likely that, from an academic viewpoint, its dangers are visible. Great numbers of physicians feel qualified to practice hygiene, and great is the mortality of medical men in the service of Hygia. He who develops no political sagacity in this environment is rejected by the people; he who acquires political sagacity of a wrong kind is rejected by the profession. Both may continue in office, but neither can be a profitable servant of the people.

Of the notable faults in American hygiene, one owes its bad eminence equally to politics and to medicine. I refer to the abject, disgraceful, ignorant poverty of American hygiene in the fundamental data of the subject. A country which swells its population by admitting a flood of immigration, with no more than a show of caution about the physical and moral results to the country, can not be expected to care about the minutiæ of loss and repair in its native population. A country which offers citizenship, on the simplest conditions, to any uncouth outlander, is not likely to learn, save in the shadow of disaster, the value of a son born in the land and nourished in its institutions for 21 years before he may become a sovereign citizen.

Excellent reasons justify four volumes of United States Census Reports on manufactures, two on agriculture, and abundant information published by state governments and class journals. Complete and accurate data on these subjects are worth many times the cost of collection. Just as satisfactory reasons justify two census volumes on population and two on vital statistics, while a great majority of the states are absolutely silent on these subjects. And such reports! Better than formerly, but beginning in 1900, as in 1890 and 1880, with an apology for 30 or 40 per cent. defectiveness of the mortality evidence, on this point, or in that locality; loaded with asterisks which mean "data insufficient;" expressing a most reasonable doubt whether nine jejune pages on births ought to be printed at all—these reports express Columbia's sense of business responsibility for 78,000,000 lives. People are cheap; worth less than the cost of acknowledging the beginning and recording the end of life. Faster than disease, accident and crime can diminish their numbers, the land can be replenished by opening the gate to cheaper people.

Vital statistics originated, as the word statistics indicates, in political science, but the neglect of the subject in this country has incited so much medical preaching that politicians have come to regard vital statistics as a kind of medical arithmetic. Such progress as registration has made in the United States is undoubtedly due to the influence of a few physicians, but it is at least doubtful whether the vital statistics of this country would improve very rapidly if wholly committed to the medical profession. Numerical completeness of returns of birth and death might be obtainable, but in a qualitative sense the results would be but little better, for the value of the results depends not on the number of observations but on their accuracy, and their accuracy depends in part on the prevailing standard of medical education, and partly on the physician's sense of responsibility in making his small contributions. In one of the United States the whole subject of sanitary government is, and from its inception has always been, in the hands of the state medical society. No state in the Union is more ignorant of its population, no state more destitute of the fundamentals of sanitary organization. To those who believe that the sanitary destinies of a state would necessarily be safe if confided wholly to physicians, the history of Alabama is a sufficient answer.

The consent of the people to systematic registration of vital data may not be easily obtained, but after that is done the consent of the medical profession will still be necessary in order that the will of the people may be effective. If in certain parts of the country the total neglect of vital registration is a vice of politics, in those states and cities where registration laws are in force, the unsatisfactory results of registration are chargeable against American medicine. To the best of my knowledge, there are two medical schools in the United States whose students are taught to write death certificates. A very intelligent professor of hygiene told me recently that it had never occurred to him that a physician might not know how to write a death certificate. My own experience in handling medical certificates of death, and my acquaintance with the results of mortality registration in general, convince me that one physician in every three can not write a good death certificate because he is not a good enough citizen, and one in every four or five can not write a good death certificate because he is not a good enough physician. Instruction concerning the medical certification of deaths would not wholly remedy these defects, for they are, I am convinced, traceable to a neglect in medical education as fundamental to the training of medical students as vital statistics are to the practice of hygiene.

The common omissions and occasional redundancies of medical certificates of death, as they have grown familiar to me, are more and more associated with the poor discipline of medical schools and hospitals in the matter of anamnesis. The habit of record-making is yet uncommon even among the younger men. Under the influence of a few schools the times are mending, but, with the exception of those who do undergraduate work in hospitals, very few medical students of to-day have any instruction whatever in medical anamnesis.

Assuming that the teachers of medicine in this country can write good death certificates, a rather large assumption, and assuming that they are able to ascertain the proficiency of students, I know of no exercise more likely to exhaust the complacency of a professor of medicine than to undertake the tabulation of a year's mortality records furnished by a hundred alumni. Whoever is greatly elated over the present status of medical science as compared with that of a generation ago may find in the "Census Manual of the International Classification of Causes of Death" an intimate and unflattering view of American medicine as revealed by American certificate of death. This work, rendered necessary because the mistaken notions of our grandfathers survive in the medical memoranda of today, shows what is probably true the world over, that the scientific advance of our generation over the last preceding, however great it may seem, can be measured by the length of a funis.

When the people have consented, and the medical profession is both willing and able to furnish memoranda concerning births and deaths, there will remain a few points for the careful consideration of hygienists. In the United States the records of public offices are apparently public in the most promiscuous sense. The laws usually state that they are open for inspection by proper persons for proper purposes. The most stringent laws hardly go further than this, and the custody of records under such loose provisions is very apt to be a nominal rather than a real guardianship.

In my first three years' experience as a registrar, access to the records was refused three times; once when information was desired to prevent a marriage, once with the design of separating a married pair, once by a physician in order to injure another physician. Later, when the records were numerically worth consulting, life insurance companies began to ask for copies of records for the purpose of verifying statements concerning the deaths of relatives made in applications for new insurance. The use of the records for this purpose was refused, and I was told that such use is constantly made of the records in all American registration offices. Thereon I sent the following inquiries to about forty American registrars:

> Are records of birth and death exposed, or copies given, to any person who may apply?
>
> Are copies of birth and death records furnished to relatives of the person named in the record without inquiry as to the reason for desiring such copies?
>
> Are copies given to attorneys or agents of relatives asking such copies of record?
>
> May a lawyer obtain a copy of a record to be used in the preparation or prosecution of an action at law to the prejudice or injury of the person named in the record or of a relative of that person?
>
> May a life-insurance agent obtain a copy of a certificate of death to complete proofs of a death claim without authority from the beneficiary to receive such information?
>
> May a life-insurance agent obtain copies of records for the purpose of verifying the statements of an applicant for insurance as to the cause of death of relatives?
>
> May a copy of a record of birth or death be obtained merely for the sake of information?

In addition to categorical answers from twenty-eight of the men addressed, I obtained a great deal of unexpected information. Those registrars who have not the permanent custody of records of births and deaths could only reply in general terms to the inquiries. None of them knew any instance of abuse of the records. In cities the situation is different. The chiefs of health departments in large cities do not know that their records are subject to any abuse. Some of them have no restrictions about furnishing information contained in the records, and no instance of misuse has come to their attention. In some cities written memorandum is made whenever a copy of record is furnished, but copies are rarely or never refused. In some cities it appears that the records may be searched by private individuals, and that no harm is known to have arisen from this complete liberty. The records are open, and no questions asked, in Indianapolis, Cleveland, Detroit, St. Paul, Milwaukee, St. Louis, Washington, New Orleans, Memphis. The purpose of the inquiry is asked in Philadelphia, Savannah, Buffalo, Louisville, Rochester and Providence, but only the registrars of Savannah, Rochester and Providence claim the power to withhold information. One can not tell from the replies of Boston, Chicago and New York whether the registrars make any inquiry as to the reason for seeking such information, or may in any case refuse information. No inquiry is made in the state of New York nor in Michigan, but the records must not be subject to loss or damage. Attempts to regulate the use of the records have been defeated in Washington, Indianapolis, Rochester, New Orleans. The privacy of the records is partly secured in Providence by a court decision; in Minnesota, by a general statute, which declares that a public official may not be examined on any information obtained in his official character if its disclosure would create public scandal. In New Jersey the records are excluded from commercial uses by regulations of the State Board of Health. In Maryland the registration law forbids the state registrar of vital statistics, under penalty of a heavy fine, to communicate any of the personal details of the records in his custody to any person not authorized to receive the same. The discretion thus vested in the registrar has sufficed so far to protect the records of births and deaths. The recent law on the registration of tuberculosis contains a similar provision. Except local health officers, no one may inspect the register of tuberculosis or receive any of the personal information contained therein without an order of court. The health officer of a western city undertook to restrict the indiscriminate use of his records for idle, or curious, or injurious purposes. The difficulties encountered were too many for him, and the records of that city may now be consulted by any one for any purpose or for no purpose. The records of this city are interesting in the fact that they contain the records both of birth and death of unacknowledged children of distinguished Americans, including a president of the United States, and the city department of health has apparently no way of preventing the inclusion of such scandalous fiction in its so-called public records. In another city the chief of the health department protects the records to the best of his ability, and in so doing has met the successful opposition of a mayor, and the threat of open war against the health department by a newspaper editor who desired to unearth a private scandal, though the records of the health department at the time included certain memoranda concerning a scandalous portion of his own life.

The state of Michigan has found it necessary to pass a special act providing for a secret calendar of marriages contracted for the purpose of legitimizing children born or expected. This seems to me only a plan of creating scandal out of materials not necessarily scandalous.

In a great many places the records of births and deaths are sold to commercial advertising agencies. Sometimes this sale has been effected secretly for a long time, but in some cities the practice is unconcealed. The buyers of these lists are milkmen, infant food and nostrum venders, tombstone makers, photographers, publishers of memorial cards, undertakers and florists. It is somewhat surprising that undertakers and florists should be willing to pay for records of death on the chance of getting business in so short a time. One registrar writes: "I do not know how it is in your state, but here I know that registrars in various parts of the country are under salary or commission by various firms to deliver regularly records of vital statistics for commercial purposes." In Baltimore an infant food vender went into court to compel the consent of the commissioner of health to the use of the birth records for advertising purposes. In the District of Columbia the commissioner of health asks Congress to pass a bill to protect the records, being unable, as matters stand, to prevent their free use for commercial purposes. In one city, a great one, an employe of the health department was found to be regularly selling to a quack the names and addresses of persons for whom sputum examinations were made in the laboratory. This practice was broken up, it is said, though its continuance was not made impossible.

If these experiences, or most of them, had been reported from the great cities, where the temptation to misuse of the records is greatest, or from the very corrupt cities where health departments may be expected to share in the political demoralization, one might conclude that these reports represented approximately the amount and kind of abuse existing in the field covered by my inquiry. But the populations in which these scandals are admitted are not especially good fields for advertising; with one exception all the cities concerned are free from notorious corruption; in two of them the stability and efficiency of the sanitary organization are remarkably high for American cities. Remember, too, that those who furnished me the information used official paper for that purpose, and it is likely that some officials would not communicate facts of the sort without precautions. It is significant also that, while one of my correspondents said that no abuse of the records had occurred in his department, a gross abuse was shortly after reported to me by another member of the same health department. That a majority of my correspondents have not heard of such abuses as I mention seems to be strange, for it is clear that such records are liable to be abused anywhere and can not be defended unless that liability is recognized.

I can not assent to the view that the records of a health department are public in the liberal sense which obtains with respect to other official records, and it seems to me vital to the sound development of our sanitary anamnesis that very close privacy should surround these personal memoranda. The records will always be false on certain particulars so long as the statements of record are open without hindrance to the general public. Precautions sufficient to prevent abuse of the records need not be so stringent as to make them less serviceable for legitimate purposes. All of us will agree, I think, that they should not be available either by gift or by purchase for commercial purposes, nor answerable to the inquiries of the malicious or mischievous or merely curious, and that records with palpably and wilfully false or slanderous contents should not be admitted to the files. Reasonable care would prevent these abuses, and it is idle to hope for healthy progress of registration until the records are reasonably safeguarded.

We dare not limit the scope of registration to the subjects now included under that head. The particulars concerning population, marriages, births and deaths are by long custom established as necessary sanitary memoranda. The registration of the graver infectious diseases, though generally provided for, is not generally practiced. From time to time the list of notifiable diseases is extended, and it is evident that the scope of registration for the purpose of hygiene will continue expanding. The formal inclusion of pneumonia, tuberculosis, malaria and cerebrospinal meningitis among the notifiable diseases, idle as it is in most places, expresses a real need in public hygiene, and not to be tolerated indefinitely among the sham defenses of American communities. It is notorious that the notification laws in most American cities are practically inoperative, and the common explanation is that the people who enacted these laws do not want them enforced. Those who assume to know the real state of public opinion are the medical practitioners, and these, indeed, do truly represent the opinions of the citizens on whom, for the time being, the notification laws are brought to bear. The consent of the well can always be counted in favor of notification, and up to this time the opposition of the sick can be as confidently expected. This brings up the humiliating reflection that the American people still expect public health to be protected by punishing the sick. It is hardly less humiliating to reflect that the medical profession, perfectly able to represent us truly to the distrustful public, suffers this medieval view to persist.

There are, however, some boards of health able to operate their notification laws with very little friction, and these have found that the opposition of the public has disappeared as fast as the confidence of the medical profession was won. Where cities have made adequate provisions for infectious diseases, where the relations of boards of health to the afflicted are altogether helpful, and, above all, where the organization of the health department is not subject to the vicissitudes of party politics, there notification laws are effective.

So far as I know, the worst forms of political corruption are very seldom discovered in health departments. I like to think that the profession to which I belong is very little inclined to cupidity, and that in hygiene, as in other branches of practical medicine, moral principles are not easily broken down. I have encountered in my own experience but a single instance of what seemed to be a conspiracy to extort a bribe involving the health department of a great city. Last October (1904) a citizen of Maryland, Mr. E. T. D., asked my assistance in the following circumstances: While on a vacation tour with his family, his son, aged 9, was attacked with diphtheria and died July 13 in a western city. He engaged an undertaker, who said that the cause of death did not prevent the transportation of the body to Maryland, and together they purchased transportation cases conforming to the interstate regulations. Permission to transport was refused by the health department on the ground that a city ordinance forbade it. There is, however, no such ordinance, though an ordinance does forbid the bringing of a body dead of diphtheria from outside into the city, and forbids the disinterment of such a body within 10 years. The Marylander was told that a permit could be obtained by "shaking hands" with the proper person. He understood this to mean the use of money, and definite instructions were given him, but when some tangible evidence of good faith was refused him he declined to do as he was instructed, bought a cemetery lot, interred the body, and returned to Maryland. He desired me to help him recover the body of his son. I gave him a letter to the western health commissioner and advised him about the legitimate cost of getting a permit. He left, saying that he would try to get his son's body without the unlawful use of money, but that if obliged to use money he would, on his return, declare all the details. In November he went west again, carrying letters from three Maryland officials besides myself. He returned with the body of his son, and on Dec. 4, 1904, told me the following story. I omit minor details: Going first to the health department, Mr. D.'s request was refused and the acceptance of his letters was refused. He went then to a railroad man of his acquaintance, who introduced him to the president of a bank, who, in turn, gave him the name and address of a lawyer. Mr. D. "shook hands" with the lawyer and gave him money for himself and several other people. He did not mention the name of the lawyer, and he implicated by name but one person, a superior officer in the health department. His resentment against this individual was very vigorous until I proposed to transmit all the information in my possession at once to the commissioner of health of that city. My fellow-citizen thereon explained that the money which he spent was in the form of gifts, and that it was possible for him to have gotten away without paying. I communicated the information in detail to the chief of the western health department. Two letters have gone each way, and such information and assistance as I can furnish are still at the service of the commissioner of health whose department is implicated in this scandalous business.

American hygiene is, as I said before, the offspring of American medicine and American politics, and is worthy of the two. While its worst faults are, perhaps, derived from politics, American medicine is measurably responsible for the moral as for the scientific deficiencies of the neglected bantling. Has the medical profession anywhere been resolutely arrayed against the corruption of American politics or ever concerned itself deeply about the welfare of its fellows exposed to extraordinary moral hazard in an honorable and necessary calling? Have the medical men who entered this field, and pursued honorable careers honorably, been defended from the predatory statesmen? Where were the physicians a few months ago, when a state, after more than twenty years of leadership in public hygiene, was turned back to the foot of the column, in order that a governor might compliment a friend?

When, "in the exigencies of politics, it seems to have been necessary, in the mind of the new mayor," to have a new commissioner of health, and to retire one of the most active and successful educators of the public that the country has produced, where were the physicians of the city? Did the exigencies of politics really score so well that physicians can hope, with a show of reason, that a new man—any new man—may succeed at once to the efficiency of his predecessor?

At the end of this chapter of delinquencies, some uninformed person may ask whether there is any virtue in American hygiene. To speak to the affirmative of that question would have been an easy and agreeable task, for I am far more impressed with the merits than with the delinquencies of American hygiene. I am as much surprised as you can be that the honor of being your chairman has turned me to these sober reflections. Pioneers we are, every one of us; fit for the trail, perhaps, but unfamiliar with it; making in the field a new science which many suppose to have been previously made in the schools and laboratories; cut off from our former associates, yet not alone, but laboring, with other pioneers of statecraft, sociology and applied science, to build the principles of preventive medicine into the social structure. Better understood, we sometimes think, by our fellow-pioneers than by the people, on one hand, or the men of medicine, on the other, ours is a game of which the players know little and the referees know less, a game having a fine theory and a book of elaborate rules, but the crudest practice. To bring the conceited medical umpire and the willful citizen-referee together and make them know each other, to mix common sense with medicine and common honesty with politics, and to let the book of rules then and there be damned; that is the way we shall come to be known for what we are, and afterward for what we ought to be. Since the robes of Æsculapius were rent by the endosmosis of common sense, we have learned that knowledge is power in proportion, not to its concentration, but to its diffusion. I count it the highest distinction of a hygienist to be diligent and skillful in diffusing among the people a special knowledge to the salvation of their bodies, and I conceive it to be within the power of this section to diffuse among medical men a general knowledge to the salvation of their citizenship.

Of my two immediate predecessors in this chair, each very clearly expressed the feeling that the Section is not now in the full exercise of its function, if, indeed, the nature of its function is generally understood. At the Atlantic City session we agreed that at each annual session the Section should make an objective presentation of some phase of its subject. Our first exhibit in this line we devoted to the hygienic relations of water. The Board of Trustees approved our plan and promised the needful financial support. At their meeting in February the Board of Trustees appropriated $200 to the use of the Section, and your Secretary and Chairman concluded that this amount would not finance such an exhibit as was planned at a point so remote as Portland. The exhibit here presented has cost the Association less than $50. The program is nearly as full as we desired, but the exhibit amounts to no more than one-tenth of what could easily have been realized. Nevertheless, the program and the exhibit meet our original design very satisfactorily in one most important respect. Both program and exhibit include contributions from non-medical sources. If some foolish person suggests that this circumstance implies a poverty of medical resources, say to such a one that it indicates, on the contrary, that affluence of hygiene which we especially desire to share with our fellows in the ranks of medicine.

If I may, in concluding, express a choice of subject for a future hygienic exhibit, I shall say that our next effort in this line should cover vital statistics, the dryest, most refractory and most neglected subject within our field, and, withal, the most necessary, the least expensive to display, and the strongest to save a man from thinking of himself more highly than he ought to think.

DISCUSSION.

Dr. Elmer E. Heg, Seattle, Wash., said that in 1890 or 1891 the first vital statistics act was passed in Washington, and it took the old form of county registration. Strenuous efforts have been made at various times to have that changed to a central registration, without any result. At the last legislature they succeeded in having a bill pass the senate, but it was amended in the house. The amendment, in Dr. Heg's opinion, absolutely killed the bill. It was very short. It was carried by an Eddyite. The original bill required that no burial permit should be issued except on the "certificate of a legally qualified physician." The christian scientist changed it so that a burial permit could be issued on the "certificate of any member of the family or a legally qualified physician." Considering that that would vitiate entirely the accuracy of death returns, Dr. Heg asked the senate committee, at conference, to refuse to concur, and the bill died in conference, so they are now just where they were in 1891. From expressions that he has heard throughout the state, Dr. Heg is satisfied that at the next legislature a proper registration act will be passed for the state of Washington. He said that, not having had a central registration, he has not been brought in contact with the illegitimate uses of the records, but he can readily see that the bill they had before the legislature would not have safeguarded them sufficiently. In the state of Washington there is no trouble at all about the notification of eruptive diseases, but when the state board of health asks for notifications of such diseases as typhoid fever or pneumonia it meets a stumbling block, and it appears to Dr. Heg that physicians ordinarily will notify the health department of any disease when the notification receives recognition by a quarantine or something of that sort, so that they know some use has been made of the notification. For the past year or two local health officers, when they were notified of typhoid fever, for instance, have placed in each house the rules of disinfection, and physicians, on receiving that much recognition of their notification, report very much better than they did before. They used to ask: "What is the use of reporting typhoid fever? It does no good." Now, when they see these rules for disinfection, they report.

Dr. W. C. Chapman, Toledo, Ohio, declared that he finds that the great trouble with physicians is want of information and want of education in the matter. Physicians all through Ohio refuse to report because they do not see that there is any necessity for doing it, and the first thing that state boards of health have to do is to educate physicians to see the necessity of reporting diseases. Dr. Chapman has had a good deal of experience in the last several years with smallpox, and the physicians say: "We will not call it smallpox till we have to." Cases of smallpox are not reported in Ohio until some one finds out that it is smallpox. Some neighbor says there is smallpox in a certain house, and the health officer finds that it is so. In Toledo there has been a good deal of smallpox among the workers in the rolling mills and iron works, because the physicians have not reported it. The people themselves will not report it. The disease has been so slight that they say: "We will not report it; we will have to go into quarantine and all that trouble." Finding that this was the case, the health officer made an inspection of that whole ward; 1,500 or 2,000 vaccinations were made, and several health officers, with the physicians, inspected the region and found a great deal of smallpox among parents and children that had not been reported. Physicians must be compelled in some way to understand the necessity of reporting diseases. In Toledo Dr. Chapman believes there is not one case in four of typhoid fever reported. In very many cases this is because of a desire on the part of the people, backed by the physicians, to avoid the notoriety. This is especially so in measles, a very dangerous disease. The medical profession is very negligent about this matter, and Dr. Chapman thinks that this Section is the one that should take steps in this matter and undertake to educate physicians and health authorities everywhere to appreciate the necessity of registration.

Dr. M. L. Price, Baltimore, suggested that what Dr. Chapman says shows that the laws of Ohio are a little lax in prosecuting these cases. In Baltimore, in smallpox and other serious contagious diseases, health authorities have been in the habit of prosecuting in every case where it is found that a report is not made. They have obtained several convictions under that law. The essential point in vital statistics is correct and accurate returns, and if that is true as to deaths it is certainly much more essential to have reports of sickness. Dr. Price regards the confidential nature of such records as absolutely essential to secure both correctness and accuracy in mortality returns. Returns in many countries do not give the correct cause of death. The returns of tuberculosis in France are practically *nil;* they are all stated as bronchitis.

Dr. Walter F. Morrison, Spokane, Wash., said that there is no law in Washington governing this subject and that, therefore, there is difficulty in getting people to conform to what the health authorities think ought to be law. In regard to reporting diseases, Dr. Morrison said that much depends on the health officer and the public sentiment behind him. In Spokane the physicians are pretty good about reporting those cases, because the health officers have taught them to do so. The health officials keep a supply of pamphlets for distribution among the physicians, and the reference to prosecutions, under the law, of physicians who do not report these cases is underlined. In several cases when there were two competing doctors in the same town who were antagonistic to each other, when one of them stated a case was scarlet fever, if slight, the other would say it was measles, or when smallpox, the other would say it was chickenpox. The trouble, Dr. Morrison thinks, is with irresponsible newspapers. These make trouble sometimes and give a good deal of annoyance when the health officers are trying their best to do their duty. Stringent quarantine laws have been established in Spokane, and they are strictly enforced, and the health department is very particular about disinfection of the premises afterward. Dr. Morrison recalled a very interesting case which occurred a short time ago, in which a girl of 16 came from an adjoining county. Three months before she came to Spokane county she had diphtheria; the town had been afflicted with diphtheria, and there was no quarantine and no disinfection in the town so far as this girl, who was very intelligent, knew. Their premises, she said, had not been quarantined and had not been disinfected. When three months time had elapsed, she thought she was safe in visiting her friends. She was suffering from conjunctivitis at the time, and came to Spokane for treatment, and within ten days of the time when she visited this family one child was attacked with membranous diphtheria and died. The mother, who had not received any antitoxin, was attacked with diphtheria and had a very severe case. In this case Dr. Morrison urged the physician to give all the members of the family immunizing doses of antitoxin. Dr. Morrison examined the girl's arm three months after she came from the house and found that a scar where she had been burned was diphtheritic, and, while there was no actual test, he is satisfied that she went to Spokane suffering from diphtheria, and that the secretions from her eyes and from this sore were diphtheritic, because within ten days two members of the family developed diphtheria and one died. He said that if there is a defect in this matter in Spokane county it is in raising quarantines too soon. He said that it is almost impossible to obtain reports on typhoid fever and tuberculosis. Dr. Morrison has not enough notices to send to the physicians in the city of Spokane who practice in the country, but sends such notices to the physicians practicing in Spokane county, without the city, and he occasionally gets a notification of tuberculosis and occasionally of typhoid fever, but there is no quarantine established. If there were some form of quarantine against typhoid fever and tuberculosis and the supposedly less severe forms of contagious diseases there would be less trouble in getting reports and enforcing health laws.

Dr. N. K. Foster, Sacramento, said that he can sympathize with Dr. Heg in his trouble in getting through the legislature laws to his liking, although the health officials' success in

California last year was a good deal better. They had been working under the old laws which were passed in 1870, under which the county recorders were expected to report to the state board of health every three months. During the last legislature they succeeded in getting passed a law providing that before the remains of a person could be legally buried the undertaker must get a permit, which is issued only on the presentation of a properly filled death certificate. This law, Dr. Foster thinks, they will succeed in enforcing. In the matter of births they will not succeed quite so well, although the law has been in effect only six weeks, and the returns are coming in pretty well. In the matter of reporting deaths they have a law that will cover the ground pretty effectually. They have followed very closely the law as suggested by the Census Bureau. The question of quarantine and the reporting of cases is one that is open to a good deal of discussion. It is a broad question, and has got two sides to it. Dr. Foster is not so much enamored with quarantine as are a good many. Take, for instance, smallpox as it has been known throughout the country for the last few years. The California state board of health has taken a little different ground than any other. When there is a case of smallpox that case must be isolated; everybody that has been exposed to the disease from that case is to be offered vaccination; if they accept it and will promise to report to the health officer every day for examination, they can go on about their work. If they refuse vaccination, then they are to be isolated, of course, not with smallpox cases, but separately, until twenty-one days have passed. In that way the health officers think that they will minimize the expense and get the maximum of protection. If isolation of every person who has been exposed is insisted on, many cases will not be reported, whereas, if the exposed ones are allowed to go about their business, there will not be that incentive to secrecy and they will accept vaccination and be protected. This method is to be given a trial. In case of diphtheria, Dr. Foster believes that the patients ought not to be let out too soon, but if the health officials say that they must stay in for six weeks they can not enforce it. The patients will say, "We won't stay." In order to make a success in reporting and controlling contagious diseases three things are necessary: Good laws, a public sentiment behind them, and an executive department that will enforce the laws. If there is a law that the public will not consent to, that it thinks is unreasonable, it can not be enforced. If the law is reasonable the physicians and the people will stand with the health officers. If there is an executive officer who will enforce those laws and once in a while make a good prosecution for the non-reporting of cases, not picking out a physician that has only a case occasionally, but the man who is at the head and not at the foot, much good can be done. By educating the people and getting good laws a condition of things can finally be obtained in which all cases will be reported, and the laws will be enforced without any great amount of trouble. It is not possible anywhere, Dr. Foster thinks, to get all tuberculosis cases reported. Dr. Foster does not believe in quarantining tuberculosis, because a person with consumption is not dangerous if he knows how to take care of himself. Efforts can be better directed to teaching people how to take care of their sputa and to make themselves safe to be with others than in quarantining them.

Dr. W. C. Chapman, Toledo, Ohio, agreed with Dr. Foster that isolation of the smallpox patient and vaccination of contacts is practical and all that is necessary. He mentioned an illustrative case.

Dr. Charles V. Genoway, Spokane, said that in a case of smallpox he would vaccinate everyone who had possibly come in contact with the patient and would take the person who had the disease to the isolation hospital. He uses serum in every case of diphtheria. He isolates the patient and gives every one who has come in contact with the case an immunizing dose of antitoxin. About the only cases of typhoid reported are those that are fatal, but he thinks they can get physicians to report those cases better than in the past. He agreed that physicians are very good in Spokane about reporting diseases. He thinks they hardly quarantine long enough for scarlet fever and diphtheria. When he went into office, ten days after the disappearance of the membrane was the rule, but he has increased that period; now it is two weeks after a culture from the throat is taken and proves negative.

Dr. Denslow Lewis, Chicago, said that the most important matter is to secure the active co-operation of the profession. It is a good many years since he was health officer of what was the village of Hyde Park and of what is now a very large portion of the South Side of Chicago. In 1879 he was health officer, and at that time many physicians objected to reporting cases because cases of infectious diseases were quarantined; cards were put up in cases of diphtheria and scarlet fever, and the smallpox patients were removed to the pest house. The families often thought it a hardship; in many instances they thought it almost a disgrace; in some cases, when the family lived in the back room of a little shop, it interfered with business, and, of course, that was most serious. In order to have statistics of value they must be complete, and for that reason it is important to have every case reported. In large cities this can only be done if the profession co-operates with the health officials; no law will make physicians report. It has been tried in Chicago; fines have been tried, and recently, in the return of vital statistics, physicians were paid, or were offered pay, for returns of births. The experience in Illinois has been very peculiar. In some towns of perhaps twenty or thirty thousand inhabitants there would be reported about twenty births a year. The prosecution of physicians will not make them do their duty; it remains, therefore, to appeal to their sense of propriety, so that an intelligent and willing co-operation may make statistical records complete. It should be understood that notification of disease does not necessarily imply that an uncomfortable quarantine shall be instituted; in other words, it is well for the health officer to exercise his judgment. At the time when Dr. Lewis was a health officer there was an epidemic of scarlet fever. He was called to see one mild case after it had been in progress a couple of weeks, when the child was practically well. The family and physician both objected to the card. They had facilities for isolation; they occupied a large house, and it was possible to put the child up in the attic away from everybody; in other words, it was possible to make the quarantine complete and to protect the public perfectly. Under those circumstances Dr. Lewis thought it advisable to omit placarding the house and no harm resulted. The health officer in these cases should have some discretionary power. The main factor is to prevent the spread of contagion, and, while it is usually advisable to secure publicity in these cases so that the public may take all due precaution, there are cases in which the placarding of houses may consistently be omitted.

Dr. L. M. Powers, Los Angeles, said that he generally advises the administration of antitoxin as a prophylactic measure in those who have been exposed to diphtheria, especially children. He is doubtful, however, whether this is a benefit to the public, though it is of undoubted benefit to the individual; it permits mild forms of diphtheria to develop, while the disease is prevented from manifesting itself sufficiently to allow the condition to be recognized and the patient isolated. Consequently these individuals may go around and infect more people than one with a malignant form would. His experience has been, not only with diphtheria, but with smallpox and typhoid fever, that the mild cases are the ones that spread the disease from town to town and over the country; therefore, he looks for mild forms of transmissible diseases which are too often not diagnosed. For years all patients with diphtheria have been separated from well persons and kept separate as far as possible by placarding the home; this is an incomplete quarantine; it is impossible to maintain a complete quarantine without a guard. By placarding the home and with no guard one can not keep people from visiting, the divine healer, christian scientist and others who wish to demonstrate their powers will take chances, and these are the people who help to disseminate the disease. Diphtheria patients in Los Angeles are not released from quarantine restrictions until they show an absence of the germ in the throat, whether that be one week, two weeks or six weeks or even eighty days. Dr. Powers has held patients in quarantine as long as eighty days, and the germs would show in a virulent form in the throat. As long as those germs exist in the throat, whether they are virulent or not, such patients are liable to transmit the disease to others with whom they come in contact. Consequently Dr. Powers thinks that quarantine restrictions should be maintained until every case shows an absence of germs at least with two consecutive cultures. In quarantining large schools or homes this procedure is necessary in order to prevent mild forms of the disease or to prevent patients who have had severe forms of diphtheria returning and reinfecting the building. The injection of small doses of antitoxin permits a mild form of the disease; the antitoxin does not kill the bacilli; it only neutralizes the toxin.

Dr. Kate Lindsay, Boulder, Colo., stated that whooping cough has been the most troublesome disease for her to quarantine, and it is a very dangerous disease, certainly during the first three years of childhood or between 6 months and 3 years. As a rule, children have whooping cough in a mild form if they are from 6 to 8 or 10 years old, and they go around the neighborhood, and yet it is a very dangerous disease in young children and very liable to be followed by sickness. Dr. Lindsay said she would like to have some light on the matter of quarantining whooping cough and saving the babies.

Dr. N. K. Foster, Sacramento, said that in California there is no law making whooping cough a quarantinable disease; it is a reportable disease under the rules of the state board, and it is a misdemeanor to disregard these rules. He also spoke of the number of properly educated sanitarians. Our health officers are largely recruited from physicians—from those who are young and inexperienced and generally without having had any special training. He said he wished the American Medical Association, starting through this Section, would insist that the medical colleges in this country educate sanitarians or at least provide some good course of sanitary science. Let them give a two years' course, so that we can have men all over the country who are competent sanitarians. Of course, there are many good men now—men who have had extended experience and education, but throughout the country sections and a good many of the thriving cities there are men who are not what is needed, and Dr. Foster supposed that it is the same throughout the United States. There is difficulty in getting men who have had any instructions whatever in sanitary science; they may be good physicians, but bad sanitarians. Dr. Foster thinks it would have to be a postgraduate course, but thinks these men should have some teaching, at least an optional course of a few months, in sanitary science.

Dr. James Carroll, Washington, D. C., said that the George Washington University is now contemplating the establishment of a course with a view to conferring the degree of doctor of public health, the special object being to qualify men for the sanitary service.

Dr. W. C. Chapman, Toledo, said that the only trouble is that health officers are not well paid. There is no inducement to take that course for two or three years for $25 a year, which is about the sum paid health officers in Ohio.

Dr. E. E. Heg, Seattle, said that Dr. Foster's idea of a course in sanitary science is exceptionally good. He thinks, however, that such a course should be a part of the general training of a physician. The whole point of getting reports is getting the co-operation of physicians; if they were to understand the necessity that the health authorities have for accurate reports there would be no trouble in getting those reports. If that was a part of the general training in colleges, a requisite for a degree, just as a knowledge of the eye is, they would know the necessity of it and education on the subject would start with the younger men. The older men would some time die off, and the younger men would know something about it. He said that Dr. Foster's method of handling smallpox in California has been done in the state of Washington for nearly three years. In Washington, on one side is a state with no health authorities whatsoever, on the other side is British Columbia, and there the authorities are exceptionally strict. If even one case of smallpox drifts over the line from any one town in Washington it means an absolute quarantine of a whole section of the state, so the Washington health officials have to be careful. All quarantine regulations should be tempered a great deal with tact. The object, of course, is to get the greatest possible protection with the least possible inconvenience. Tact is a valuable quality in any health officer or in any physician.

Dr. Charles C. Browning, Monrovia, Cal., said that co-operation has been dwelt on at length, and he thinks not too greatly, because that lies at the foundation of being able to secure reports. Recently he was visiting a physician, who was going to stop at a place, and asked him to step in. He stepped in and saw a child with scarlet fever and was a little surprised. The physician made a hurried call, and after leaving the case said he would not call it scarlet fever because the health officer would put a card on that house, and the man had to make a living. It seems in that particular town the physicians are not in as good accord as they are in Washington. That is one of the stumbling blocks. Another is that the people generally understand that a report means quarantine. Now, the large number of cases of tuberculosis and typhoid fever do not need to be quarantined in the general sense of the term; it is not proper or necessary, but if physicians understand that when such cases are reported a certain latitude and assistance will be extended, the disease will be attacked by educating the people. First get the physicians educated, and then educate the people to look on the health authorities as their friends, and not as a great inconvenience. That is especially true of typhoid fever and tuberculosis, diseases which are responsible for a great deal of suffering. Then get at the teachers of the public schools through the state board of health and through the county and city boards.

INNOCENT FIBROMYOMA OF THE UTERUS.*

THOMAS B. EASTMAN, M.D.
INDIANAPOLIS.

During the last few years there has appeared in the surgical literature a number of articles wherein the writers have advocated the removal of practically all fibromyomata of the uterus. This position has been taken for the most part on the ground that in many cases complications threatening life, such as the various diseases of the tubes and ovaries, etc., were found which warranted the removal of these structures together with the uterus itself.

It is my purpose to urge that in a very large proportion or in practically all fibroid tumors there exists in the tumor itself at the time of diagnosis, or will exist with considerable degree of certainty at some future time, conditions which warrant their removal, or that the tumor will sooner or later produce such conditions elsewhere. I do this with the full realization that there come to the autopsy room numerous cases wherein such tumors had existed for years symptomless, and in which they were no way responsible for the death of the woman.

That there is a tendency to exaggerate the extent to which these degenerations are found is conceded; nevertheless, that they are found in such a number of cases as to render them of much importance requires for confirmation only the careful perusal of the literature of the subject.

Camus[1] reports a case of multiple fibromyoma of the uterus, weight 4 kilograms, which had undergone calcareous degeneration in one part, the degeneration evidently having started on the periphery. There were no symptoms, but large abdomen.

M. Cornil[2] describes the removal of an intramural fibroid of the size of a fist in a state of edematous and colloid degeneration. The tissue was semitransparent and soft. The uterine cavity was filled with a cancerous growth, bathed in a milk-like liquid. (Microscopic examination.)

Haultain[3] believes that while fibromyomata may become secondarily malignant, this is by no means so common as might be inferred. Authentic thoroughly proved cases of sarcomatous change in a pre-existing fibroid are few, yet it is probable that all cases of encapsulated sarcomata are degenerating fibromyomata.

Von Franke[4] states that sarcomatous degeneration occurs in .75 per cent. of all cases, while Cullingworth met with one case of myxosarcoma in 300 cases of fibroid, and Noble only two in 258 cases. Von Franke has observed one undoubted case in 400, while in consulting the case book statistics of Professor Simpson's ward in the Edinburgh Royal Infirmary no instance has occurred in the last 300 cases of fibromyoma. In taking these statistics *en masse,* in only four cases out of 1,250 fibromyomata had sarcomatous change occurred. As a rule, he states, sarcomatous change occurs after or about the menopause and is perhaps the most common, but by no means the only cause of increase in size of a fibromyoma after the climacteric. From the rapid increase in the size of the tumor, severe pain is a very constant symptom. Thus, if after the menopause along with enlargement of a known fibroid there is pain and loss of strength, the diagnosis of sarcomatous change is almost certain. Cystic edematous infiltration and degeneration of fibroids with slight cellular proliferation resembling myxosarcoma, von Franke has observed on two occasions. In one of these, the interspaces were filled with a blood clot which gave the appearance of a telangiectatic tumor described first by Cruveilhier. In both cases the cellular proliferation, though assuming the embryonic type, was so scanty that one could hardly classify them as sarcomata. After removal there has been no sign of recurrence as was to be expected. He believes that malignant epithelial infiltration of fibromyomata is of extreme rarity, only one or two cases having been cited. In these instances, the original tumor has probably been adenomyoma, a tumor either due to Wolffian relics or to infiltration of the muscularis of the uterus by glands from the endometrium.

H. Smith[5] reports a case of calcareous degeneration of a fibroid tumor removed by supravaginal laparotomy. Recovery.

Dr. B. Fenwick[6] noticed that calcareous tumors invariably had very small pedicles and in cases he examined he found that the blood vessels were of a small caliber in comparison with the size of the tumor they had to supply. He thought, therefore, that the cause of degeneration was the want of an adequate blood supply. The walls of the ovarian and uterine vessels in cases of myoma were almost invariably greatly thickened, a condition described still more clearly by Mr. Stanhope Bishop more recently. Adhesions to the intestines and omentum were less common in calcareous cases than when the degeneration was more rapid.

B. Emmett[7] describes a fibromyoma filling the pelvis and a greater portion of the abdomen, causing pressure symptoms. One of the tumors was found on microscopic examination to have undergone colloid degeneration. Dr. Dougal Bissell mentioned two cases.

Francois Dainville[8] reports a case of cancerous degeneration of fibromyoma of the uterus.

Charles P. Noble[9] reports a case of the invasion of a fibromyoma of the uterus by an adenocarcinoma, which by metaplasia had assumed the appearance of a squamous cell carcinoma. There was an absence of cancer elsewhere in the body. He considers the important point in connection with this tumor to be the question of origin of the epithelial masses, and mentions the following sources reported in the literature:

1. Metastasis from tumor in other parts of the body. Such an extension has been reported by Schraper[10] from primary cancer of the lung.

2. Extension to myoma of cancer of uterus. Cases are reported by Bubl,[11] Röhrig,[12] Cullen,[13] Ruge and Veit.[14]

3. In the development of cancerous tumor from epithelium normally contained in fibromyoma of this type, the "myocarcinom" described by Liebmann[15] is not satisfactorily explained. Rolly[16] describes an intramural myoma presenting the picture of carcinoma, with metastasis in the liver and bones. The uterine mucosa was normal. He believed the uterine tumor to be primary and to have its origin in adenomyoma, which in turn had developed from the remnants of the Wolffian body. Complete physical examination showed no evidence of tumor in other organs, and the portion of cervix not removed appeared normal. Microscopic examination showed distinct evidence of development from the epithelium covering the tumor.

J. C. Webster[17] lists 210 cases of fibroid tumors treated surgically in which the degenerations were as follows: Calcareous 2, edematous 6, cystic 13, myomatous 4, suppurating 10, adenocarcinoma of cervix 1. sarcoma 2, hemorrhagic 3, necrobiosis 11; total 52.

Webster compares these findings with those of some other workers who have given particular attention to the subject in recent years. Thus Scharlieb in 100 cases of fibroid found degenerations in 26; Cullingworth in the same number found it in 52; Noble in 258 cases, found it in 47; Ellice McDonald in 280 cases, found it in 135.

E. McDonald[18] writes: "Since Martin in 1888 made his study of degeneration in 205 cases of fibromyomata, others have reported similar series; notably Noble[19] 258 cases, C. J. Cullingworth[20] 100 cases, Mary Scharlieb[21] 100 cases, and C. C. Frederick[22] 125 cases."

He summarizes the degenerations as follows: Fatty degeneration 7, calcareous infiltration 11, necrosis 55. cystic degeneration 34, telangiectasis 46, sarcoma 17. associated carcinoma of the cervix 15, associated carcinoma of the body 17, myxomatous (edematous) 8, associated syncytioma 1; total 788.

McDonald found degenerations as follows: Slight hyalin 18, moderately hyalin 32, marked hyalin 19. hyalin and calcareous 8, calcareous 14, calcareous, necrotic, hemorrhagic 2, cystic 8, myxomatous 4. hemorrhagic 6, necrotic 4, necrotic and hyalin 3, necrotic and not, such patients are liable to transmit the disease to others with whom they come in contact. Consequently Dr. Powers thinks that quarantine restrictions should be maintained until every case shows an absence of germs at least with two consecutive cultures. In quarantining large schools or homes this procedure is necessary in order to prevent mild forms of the disease or to prevent patients who have had severe forms of diphtheria returning and reinfecting the building. The injection of small doses of antitoxin permits a mild form of the disease; the antitoxin does not kill the bacilli; it only neutralizes the toxin.

Dr. Kate Lindsay, Boulder, Colo., stated that whooping cough has been the most troublesome disease for her to quarantine, and it is a very dangerous disease, certainly during the first three years of childhood or between 6 months and 3 years. As a rule, children have whooping cough in a mild form if they are from 6 to 8 or 10 years old, and they go around the neighborhood, and yet it is a very dangerous disease in young children and very liable to be followed by sickness. Dr. Lindsay said she would like to have some light on the matter of quarantining whooping cough and saving the babies.

Dr. N. K. Foster, Sacramento, said that in California there is no law making whooping cough a quarantinable disease; it is a reportable disease under the rules of the state board, and it is a misdemeanor to disregard these rules. He also spoke of the number of properly educated sanitarians. Our health officers are largely recruited from physicians—from those who are young and inexperienced and generally without having had any special training. He said he wished the American Medical Association, starting through this Section, would insist that the medical colleges in this country educate sanitarians or at least provide some good course of sanitary science. Let them give a two years' course, so that we can have men all over the country who are competent sanitarians. Of course, there are many good men now—men who have had extended experience and education, but throughout the country sections and a good many of the thriving cities there are men who are not what is needed, and Dr. Foster supposed that it is the same throughout the United States. There is difficulty in getting men who have had any instructions whatever in sanitary science; they may be good physicians, but bad sanitarians. Dr. Foster thinks it would have to be a postgraduate course, but thinks these men should have some teaching, at least an optional course of a few months, in sanitary science.

Dr. James Carroll, Washington, D. C., said that the George Washington University is now contemplating the establishment of a course with a view to conferring the degree of doctor of public health, the special object being to qualify men for the sanitary service.

Dr. W. C. Chapman, Toledo, said that the only trouble is that health officers are not well paid. There is no inducement to take that course for two or three years for $25 a year, which is about the sum paid health officers in Ohio.

Dr. E. E. Heg, Seattle, said that Dr. Foster's idea of a course in sanitary science is exceptionally good. He thinks, however, that such a course should be a part of the general training of a physician. The whole point of getting reports is getting the co-operation of physicians; if they were to understand the necessity that the health authorities have for accurate reports there would be no trouble in getting those reports. If that was a part of the general training in colleges, a requisite for a degree, just as a knowledge of the eye is, they would know the necessity of it and education on the subject would start with the younger men. The older men would some time die off, and the younger men would know something about it. He said that Dr. Foster's method of handling smallpox in California has been done in the state of Washington for nearly three years. In Washington, on one side is a state with no health authorities whatsoever, on the other side is British Columbia, and there the authorities are exceptionally strict. If even one case of smallpox drifts over the line from any one town in Washington it means an absolute quarantine of a whole section of the state, so the Washington health officials have to be careful. All quarantine regulations should be tempered a great deal with tact. The object, of course, is to get the greatest possible protection with the least possible inconvenience. Tact is a valuable quality in any health officer or in any physician.

Dr. Charles C. Browning, Monrovia, Cal., said that co-operation has been dwelt on at length, and he thinks not too greatly, because that lies at the foundation of being able to secure reports. Recently he was visiting a physician, who was going to stop at a place, and asked him to step in. He stepped in and saw a child with scarlet fever and was a little surprised. The physician made a hurried call, and after leaving the case said he would not call it scarlet fever because the health officer would put a card on that house, and the man had to make a living. It seems in that particular town the physicians are not in as good accord as they are in Washington. That is one of the stumbling blocks. Another is that the people generally understand that a report means quarantine. Now, the large number of cases of tuberculosis and typhoid fever do not need to be quarantined in the general sense of the term; it is not proper or necessary, but if physicians understand that when such cases are reported a certain latitude and assistance will be extended, the disease will be attacked by educating the people. First get the physicians educated, and then educate the people to look on the health authorities as their friends, and not as a great inconvenience. That is especially true of typhoid fever and tuberculosis, diseases which are responsible for a great deal of suffering. Then get at the teachers of the public schools through the state board of health and through the county and city boards.

INNOCENT FIBROMYOMA OF THE UTERUS.*

THOMAS B. EASTMAN, M.D.
INDIANAPOLIS.

During the last few years there has appeared in the surgical literature a number of articles wherein the writers have advocated the removal of practically all fibromyomata of the uterus. This position has been taken for the most part on the ground that in many cases complications threatening life, such as the various diseases of the tubes and ovaries, etc., were found which warranted the removal of these structures together with the uterus itself.

It is my purpose to urge that in a very large proportion or in practically all fibroid tumors there exists in the tumor itself at the time of diagnosis, or will exist with considerable degree of certainty at some future time, conditions which warrant their removal, or that the tumor will sooner or later produce such conditions elsewhere. I do this with the full realization that there come to the autopsy room numerous cases wherein such tumors had existed for years symptomless, and in which they were no way responsible for the death of the woman.

That there is a tendency to exaggerate the extent to which these degenerations are found is conceded; nevertheless, that they are found in such a number of cases as to render them of much importance requires for confirmation only the careful perusal of the literature of the subject.

Camus[1] reports a case of multiple fibromyoma of the uterus, weight 4 kilograms, which had undergone calcareous degeneration in one part, the degeneration evidently having started on the periphery. There were no symptoms, but large abdomen.

M. Cornil[2] describes the removal of an intramural fibroid of the size of a fist in a state of edematous and colloid degeneration. The tissue was semitransparent was much more thickened and of brainlike consistency. On microscopic section extending from this area outward and involving the uterine musculature and the tumor growth, there were numerous projections which showed carcinomatous degeneration. In addition to this there were areas entirely cut off from the endometrium and surrounded by the fibrous tissue in which the alveoli were easily made out. This patient, operated on in March, is already showing evidence of return of the growth.

[2] Bull. et Mém. Soc. An., Paris, 1904, lxxix, 696.

Case 6.—A woman aged 43 suffered but slightly from a tumor not larger than an orange. This tumor on removal proved not only to have undergone extensive calcareous degeneration, but telangiectatic degeneration also, so that the hemorrhage was excessive owing to the dilatation of the blood vessels as well as from the fact that the calcareous degeneration seemed to have invaded the vessel walls. The conditions found in this growth do not bear out the statement by Fenwick previously quoted. He holds that in calcareous tumors we usually find the blood vessels of small caliber.

Case 7.—This patient had a fibroid some 10 inches in its transverse diameter. In shape it was very much like an enormous kidney, attached by its hilum as it were, to the fundus of the uterus, the pedicle being some three inches in diameter. This tumor had been of little or no trouble to the woman until she had a fall, after which the symptoms of torsion of the pedicle appeared. The tumor was promptly removed and showed evidences of necrobiotic degeneration.

These cases all present one common characteristic, the lack of any symptom which would indicate any pathologic lesion other than the tumor itself. In one case, the patient was not aware that she had a tumor; yet of these cases, two patients died for want of an operation; one from necrotic changes, the other from changes in the myocardium, which condition, according to eminent authorities, is undoubtedly one of the results of neglected fibromyomata. Another of these cases illustrates a common form of the innocent fibroid, the tumor attached to the fundus by a long pedicle. By virtue of such attachment, it is little calculated to give rise to symptoms so long as it remains in its original position. There is ordinarily no menorrhagia. As it assumes some size, it rises easily out of the pelvis. It causes no pressure symptoms, but its very conformity makes it particularly prone to circulatory changes either from a deficient blood supply through its narrow pedicle or by torsion of the latter.

Of these cases, two patients died without an operation in which there were at least nine chances out of ten for recovery. One will die after the operation as the result of a general carcinomatosis appearing promptly after the removal of a fibroid tumor which had been extensively invaded by carcinoma from the endometrium. The others are alive and well. They are all of the class in which those operators who believe in the policy of procrastination, or who, to use their own expression, take a classical view of these cases, would have advised against operation.

It is hard to realize in this day of advanced and intelligent surgery that men of unquestioned standing will delay these operations, trusting to good luck or the menopause to do away with the symptoms of which these women complain. According to my observations, so far as the menopause is concerned, it aggravates rather than improves the symptoms in at least half the cases. The idea of the menopause curing such a thing as a fibromyoma is a relic of the surgical dark ages, and admitting the bare possibility of such a thing occurring, the chance is so small that it should not be taken by the intelligent modern operator.

In this connection, J. Bland Sutton[26] says: "Surely there is nothing in the whole range of surgery more ironical than a woman spending 20 or even 30 years of her life as a chronic invalid on account of a uterine fibroid, in the expectation that at the menopause she will be restored to health and begin a new life, and then to realize that, far from this being fulfilled, the fibroid becomes necrotic, extruded or septic, and places her life in the gravest peril, and that she may die in spite of surgical intervention."

John B. Deaver[27] says: "The mere fact that a woman has a fibroid tumor of the uterus is in no respect, however, an indication for its removal." In his opinion, no such growth should be removed unless it causes symptoms. In the seven cases mentioned above, there were at the time of examination practically no symptoms, yet as already stated, two of the patients died without operation; one from a degeneration, the other from a complication superinduced by the tumor and in the other five, operation revealed conditions which, had operation not been made, must necessarily have resulted in death or in an operation made on a patient whose vitality had been lowered by disease.

Deaver also states that he is thoroughly convinced that a myoma of the uterus which produces no symptoms is as nearly harmless as any pathologic change can ever be. It will be readily granted that a myoma is harmless as long as it remains harmless, but when one takes into consideration the large proportion of these tumors, which, according to statistics which must be accepted as accurate, do undergo degenerative changes, it is at once evident that time alone is necessary to affect pathologic changes threatening life. So far as the innocent fibroid is concerned, there is nothing so innocent, nothing so treacherous.

In respect to the statement that the dead house reports show large numbers of fibroids with which the women lived a long life in perfect contentment, Noble of Philadelphia says: "For those who are convinced that one of the classical position is correct, I would suggest that one of the strongest arguments that could be produced in support of their position would be to institute a careful research into the autopsy records of well-managed institutions in order to learn, first, in what proportion of women fibroid tumors are found at autopsy, and, second, what relation these tumors had to the state of health or to the death of the particular patients. It is a classical statement that many women live and die without the knowledge that they have had fibroid tumors. This statement I do not believe, but I would be quite willing to be convinced of its truth on adequate evidence."

Deaver further states, quoting McDonald's article, wherein he reports a series of microscopic studies of 280 cases, that there were 12 cases, or 4.28 per cent. of malignant degenerations; add to these the 14 cases of calcareous degeneration and the 4 necrobiotic degenerations, which conditions under the circumstances, in great probability, would result fatally, not to mention the other degenerations listed, we have 30 cases, or 10.7 per cent. A consideration of other statistics will give practically similar percentages. It is not possible, of course, to say how many of these patients Deaver would have operated on, but it is fair to assume that the diagnosis of the degenerations was not made in all of them before operation. In the same paper he reports a series of 105 cases, with a mortality of 2.85 per cent. His own small death rate is sufficient answer to his argucystic infected 1, adenomyoma 6, associated with adenocarcinoma 6, associated with squamous cell carcinoma of the cervix 2, sarcoma 3, deciduoma malignum 1; total 135.

---

[26] The Lancet, June 6, 1903.

[27] Amer. Med., vol. 9, No. xv, page 601.

He concludes as follows:

1. Fibroids producing symptoms and all fibroids except those designated as small (especially when subserous or intramural) should be removed because the risk to the patient from operation is far less than from the tumors themselves.
2. In view of the sarcomatous changes, carcinomatous associations and complications of uterine fibromyomata, early removal is indicated when they are of sufficient size to produce symptoms.
3. Thorough pathologic examination should be made of all fibroids for evidence of malignancy. Particular study should be devoted to those tumors which are necrotic, cystic, or both, as among these are found the largest proportion of malignant changes.

Charles P. Noble[23] of Philadelphia, says A. Martin[24] was probably the first to tabulate and to analyze degenerations of uterine fibroids, as follows: Fatty degenerations 7, calcification 3, suppuration 10, edema 11, cystic degeneration 8, telangiectasis 3, sarcoma 6, carcinoma of the cervix 2, carcinoma of the body 7; total 57.

Dr. Noble tabulated and analyzed 258 cases of both degenerations and complications. He classes these in three groups:

1. Those which would lead to a fatal result.
2. Those which would threaten the life of the patient.
3. Those which would involve more or less invalidism.

He estimated that 95 of these patients, or 36 per cent., would have died of the complications of the fibroid tumors had they not been operated on.

Charles J. Cullingworth[20] reports 100 cases, covering a period from 1892 to 1901, inclusive; of these 46 were typical fibromyomata, with no structural change evident to the naked eye; two showed telangiectatic change, and 52 presented pathologic degenerations, as follows: Edematous and myxomatous 27, myxosarcomatous 1, cystic or fibrocystic 5, calcareous 1, necrotic 18; total 52.

Pain as a predominant symptom is an indication of a degenerative process. The age of the youngest patient operated on was 28, the eldest 61; the preponderant ages 35 and 45. Two of the cases showed a marked increase in size after the onset of the menopause, with initiation of necrotic change at that period. The operation resulted fatally in both these cases. No conclusions are formulated.

Carleton C. Frederick[22] reports a series of 125 cases of both degenerations and complications. An estimate of probably 30 fatalities from complications alone may be made or about 45 per cent. from all complications.

Mary Scharlieb[21] reports in 100 cases the following degenerations and complications: Edematous and myxomatous 5, sarcomatous 6, cystic or fibrocystic 7, calcareous 2, necrotic 2, sloughing 3, carcinomatous 1; total 26.

Degenerations were found in one-fourth of the patients operated on; in one-half of these it was such as directly to threaten the life of the patient without any reference to hemorrhage or pressure effects. In two patients the tumors contained cysts and were also invaded by sarcoma. In 55 cases calcareous and sarcomatous changes had occurred. The age of the youngest patient was 18 years, that of the eldest 68.

In my 169 cases, degenerations were found as follows: Necrobiotic 10, sarcomatous 1, suppurative 1, calcareous 2, myxomatous 3, adenocarcinoma of body 3, telangiectatic 4, cystic 7; total 31.

Out of these 169 cases, I wish briefly to outline five cases which illustrate the impracticability and often the impossibility of a diagnosis of certain conditions in these growths prior to removal; also two patients not operated on at the time of the first examination, owing partly to the unwillingness to submit to operation and partly to an ill-advised deference on my part to the so-called classical teaching in the treatment of symptomless fibromyomata. The latter two patients died without operation.

Case 1.—The patient came to me for consultation with regard to an abdominal tumor which on examination proved to be an interstitial fibromyoma of the uterus extending well up toward the umbilicus. She had few symptoms; her heart sounds were normal; her chief complaint was of the weight. There were no disturbances of menstruation. I advised operation, to which the patient demurred, saying it was giving her little or no trouble and she would not take the risk. A year later she appeared eager for an operation. A glance gave evidence that an operation was out of the question. Six weeks later she died; an autopsy revealed fatty degeneration of the myocardium. According to various authors[25]—(Hofmeyer, Fehling, Dower, Fenwick[6])—heart degenerations are a common result of neglected fibromyomata.

Case 2.—An unmarried woman came to me with a fibroid tumor of considerable size not because she suffered from it, but because her neighbors were questioning her chastity. This was in the summer, and she preferred to wait until cooler weather for operation. Before the oncome of such weather as suited her, however, she was seized with a chill, followed by high temperature and rapid pulse, and died. Autopsy here showed extensive necrobiotic changes.

Case 3.—This patient, aged 38, came to me complaining of a not particularly severe menorrhagia. There was some history of malaria. She did not know she had a tumor. Examination, however, revealed a uterine fibroma about the size of a cocoanut, low in the pelvis, with subserous nodules protruding from the surface of the larger mass. On removal the mass showed at various places throughout its interior small areas of softening which were easily indented, while the tissues had a tendency to break down on pressure. Microscopic sections through these areas showed plainly that the tissues had a tendency to break down on pressure. Microscopic sections through these areas showed plainly that the tissues were undergoing necrobiotic changes.

Case 4.—A colored woman, aged 45, had a tumor which extended well above the umbilicus. She suffered considerably from menorrhagia and from pressure symptoms, although there was nothing in her condition which could be construed as threatening. As a matter of fact she was able to sustain herself and a rather large family by work at the washtub. A superficial examination of the tumor after its removal indicated that it was nothing more than a simple fibromyoma. A series of sections from different portions of the mass examined under the microscope, however, showed areas in which there were distinct evidences of sarcomatous degeneration.

Case 5.—This patient also was a negress, aged 23, from whose sister I had a year before removed a fibromyoma, and this fact was probably responsible for her coming to me at a time when the tumor, so far as she knew, was giving her no trouble, although she was rapidly declining in health, a condition which she attributed to other causes. The tumor was of the interstitial variety and measured about 3 by 4 inches. On section the endometrium was found to be very much thickened, while high up in the cavity there was a small mucous polyp, in the neighborhood of which the endometrium was much more thickened and of brainlike consistency. On microscopic section extending from this area outward and involving the uterine musculature and the tumor growth, there were numerous projections which showed carcinomatous degeneration. In addition to this there were areas entirely cut off from the endometrium and surrounded by the fibrous tissue in which the alveoli were easily made out. This patient, operated on in March, is already showing evidence of return of the growth.

[24] "Pathology and Therapeutics of Diseases of Women," Boston, 1890, pp. 268-272.

[25] Jour. Obst. and Gyn., 1902, ii, 223.

CASE 6.—A woman aged 43 suffered but slightly from a tumor not larger than an orange. This tumor on removal proved not only to have undergone extensive calcareous degeneration, but telangiectatic degeneration also, so that the hemorrhage was excessive owing to the dilatation of the blood vessels as well as from the fact that the calcareous degeneration seemed to have invaded the vessel walls. The conditions found in this growth do not bear out the statement by Fenwick previously quoted. He holds that in calcareous tumors we usually find the blood vessels of small caliber.

CASE 7.—This patient had a fibroid some 10 inches in its transverse diameter. In shape it was very much like an enormous kidney, attached by its hilum as it were, to the fundus of the uterus, the pedicle being some three inches in diameter. This tumor had been of little or no trouble to the woman until she had a fall, after which the symptoms of torsion of the pedicle appeared. The tumor was promptly removed and showed evidences of necrobiotic degeneration.

These cases all present one common characteristic, the lack of any symptom which would indicate any pathologic lesion other than the tumor itself. In one case, the patient was not aware that she had a tumor; yet of these cases, two patients died for want of an operation; one from necrotic changes, the other from changes in the myocardium, which condition, according to eminent authorities, is undoubtedly one of the results of neglected fibromyomata. Another of these cases illustrates a common form of the innocent fibroid, the tumor attached to the fundus by a long pedicle. By virtue of such attachment, it is little calculated to give rise to symptoms so long as it remains in its original position. There is ordinarily no menorrhagia. As it assumes some size, it rises easily out of the pelvis. It causes no pressure symptoms, but its very conformity makes it particularly prone to circulatory changes either from a deficient blood supply through its narrow pedicle or by torsion of the latter.

Of these cases, two patients died without an operation in which there were at least nine chances out of ten for recovery. One will die after the operation as the result of a general carcinomatosis appearing promptly after the removal of a fibroid tumor which had been extensively invaded by carcinoma from the endometrium. The others are alive and well. They are all of the class in which those operators who believe in the policy of procrastination, or who, to use their own expression, take a classical view of these cases, would have advised against operation.

It is hard to realize in this day of advanced and intelligent surgery that men of unquestioned standing will delay these operations, trusting to good luck or the menopause to do away with the symptoms of which these women complain. According to my observations, so far as the menopause is concerned, it aggravates rather than improves the symptoms in at least half the cases. The idea of the menopause curing such a thing as a fibromyoma is a relic of the surgical dark ages, and admitting the bare possibility of such a thing occurring, the chance is so small that it should not be taken by the intelligent modern operator.

In this connection, J. Bland Sutton[26] says: "Surely there is nothing in the whole range of surgery more ironical than a woman spending 20 or even 30 years of her life as a chronic invalid on account of a uterine fibroid, in the expectation that at the menopause she will be restored to health and begin a new life, and then to realize that, far from this being fulfilled, the fibroid becomes necrotic, extruded or septic, and places her life in the gravest peril, and that she may die in spite of surgical intervention."

John B. Deaver[27] says: "The mere fact that a woman has a fibroid tumor of the uterus is in no respect, however, an indication for its removal." In his opinion, no such growth should be removed unless it causes symptoms. In the seven cases mentioned above, there were at the time of examination practically no symptoms, yet as already stated, two of the patients died without operation; one from a degeneration, the other from a complication superinduced by the tumor and in the other five, operation revealed conditions which, had operation not been made, must necessarily have resulted in death or in an operation made on a patient whose vitality had been lowered by disease.

Deaver also states that he is thoroughly convinced that a myoma of the uterus which produces no symptoms is as nearly harmless as any pathologic change can ever be. It will be readily granted that a myoma is harmless as long as it remains harmless, but when one takes into consideration the large proportion of these tumors, which, according to statistics which must be accepted as accurate, do undergo degenerative changes, it is at once evident that time alone is necessary to affect pathologic changes threatening life. So far as the innocent fibroid is concerned, there is nothing so innocent, nothing so treacherous.

In respect to the statement that the dead house reports show large numbers of fibroids with which the women lived a long life in perfect contentment, Noble of Philadelphia says: "For those who are convinced that one of the classical position is correct, I would suggest that one of the strongest arguments that could be produced in support of their position would be to institute a careful research into the autopsy records of well-managed institutions in order to learn, first, in what proportion of women fibroid tumors are found at autopsy, and, second, what relation these tumors had to the state of health or to the death of the particular patients. It is a classical statement that many women live and die without the knowledge that they have had fibroid tumors. This statement I do not believe, but I would be quite willing to be convinced of its truth on adequate evidence."

Deaver further states, quoting McDonald's article, wherein he reports a series of microscopic studies of 280 cases, that there were 12 cases, or 4.28 per cent. of malignant degenerations; add to these the 14 cases of calcareous degeneration and the 4 necrobiotic degenerations, which conditions under the circumstances, in great probability, would result fatally, not to mention the other degenerations listed, we have 30 cases, or 10.7 per cent. A consideration of other statistics will give practically similar percentages. It is not possible, of course, to say how many of these patients Deaver would have operated on, but it is fair to assume that the diagnosis of the degenerations was not made in all of them before operation. In the same paper he reports a series of 105 cases, with a mortality of 2.85 per cent. His own small death rate is sufficient answer to his argument. Is it at all probable that the death rate would have been so small had these patients, whose cases he quotes from McDonald's table, not been operated on as soon as the tumor was diagnosticated? Take the five cases of so-called harmless fibroids which I list out of a series of 169 cases. Would these patients not all have died without operations?

---

[26] The Lancet, June 6, 1903.

[27] Amer. Med., vol. 9, No. xv, page 601.

It is a matter of curiosity as to what those operators who assume what Noble refers to as the classical or traditional attitude, do with other conditions in the abdominal cavity, conditions which are analogous in every respect to the so-called harmless fibroid. Recently I removed from a woman aged 73 an ovarian tumor weighing, with its contents, 30 pounds. She had carried this tumor for 25 years; she had never had any symptoms from it and was able to earn her own living. Would these classicists have allowed it to remain? They remove appendices in the interval, and small ovarian cysts; they remove symptomless gallstones from the gall bladder, not on account of any immediate danger, but on account of the fact that in no greater proportion than in fibromyomata of the uterus these various conditions will undergo changes threatening the life of the patient. For the same reason I remove all fibromyomata of the uterus.

In conclusion, considering the statistics, the accuracy of which can not be doubted, the low death rate in hysterectomy in the hands of competent operators and in cases not too long neglected, and particularly the fact that many of these tumors on removal reveal conditions threatening death, and which are not suspected, and can not be diagnosticated prior to operation, I am convinced that all fibromyomata should be removed unless there be concurrent conditions which render the operation inadvisable.

DISCUSSION.

Dr. Frank T. Andrews, Chicago, said that he is absolutely opposed to the position taken by Dr. Eastman, because it is so dangerous that it is vicious. He has seen many patients go by the menopause; in fact, it is his hope to carry them past the menopause and to watch them get well, and the vast majority do get symptomatically well. It is impossible to say in how many of Dr. Eastman's cases the tumors would have become cancerous if let alone. Few of these cases develop into sarcoma.

Dr. W. F. B. Wakefield, San Francisco, declared that he is absolutely in accord with everything Dr. Eastman said. His is true, up-to-date teaching.

Dr. J. H. Carstens, Detroit, asked in how many cases the growths undergo changes of various kinds, the result of interference with the circulation, and how many patients in a hundred will die if operated on. In his opinion more patients will undergo a change for the worse in the way of malignancy, septic conditions and adhesions if they are not operated on than would die if they were operated on. There is another thing to consider. A fibroid tumor is not appendicitis. An operation for fibroid ordinarily is not dangerous and one can select the time for operation. The patient can be put in such a condition that the operation will be almost free from any danger, and a man may be selected who is thoroughly competent to do the operation. The mortality will then be so small that the point made by Dr. Eastman is well taken. Every orthopedic surgeon operates on club feet, knock knees and deformities of all kinds in which the mortality is as great, and even greater, than it is in operations for fibroid. He operates for esthetic purposes or to restore lost functions, and the operation is justifiable. If the patient is young the tumor should be enucleated; if she is old the uterus and whatever else may be necessary should be removed. To let a woman go around with a tumor for ten or fifteen years is not good practice. It is the physician's duty to relieve the mental condition of that woman, to ease her mind and to make her mentally and physically comfortable. The patient, however, must be in good condition before an attempt is made to remove the fibroid.

Dr. L. H. Dunning, Indianapolis, agreed with Dr. Eastman in the main, but he would not like to be committed to the dictum that physicians should operate on every case of fibroid. It is true that 18 per cent. of fibroids undergo a dangerous degeneration, and, on the other hand, fibroid tumor operations—hysterectomy and myomectomy—do not, under favorable circumstances, give a mortality of more than 5 per cent.; that is to say, 13 per cent. is gained by the operative method. Many patients carry fibroids for fifteen or twenty years without any knowledge of the fact. They discover them accidentally when they are near the menopause. Many physicians have patients to show that 80 per cent. of fibroids undergo benign degeneration and absorption after the menopause. Given a woman 40 years of age, not suffering from the tumor, Dr. Dunning asked if gynecologists are not justified in assuring that woman that the probabilities are 80 per cent. in her favor that the tumor will disappear without harm to her. He would be exceedingly loth to undertake the removal of a tumor that produces no symptoms. If degeneration is taking place the signs are growth of the tumor, pain, fever, cachexia, increase of menstruation and painful menstruation. Dr. Dunning is of the opinion, based on considerable experience, that physicians are justified in many cases, especially when the patient is near the menopause, in watching the case, allowing the patient to go without operation when there are no symptoms. These patients, as a rule, take the matter cheerfully, and after the menopause their troubles gradually disappear.

Dr. D. H. Craig, Boston, stated that to propose the rule of operating in every case of fibroid is as much empiricism as is the administration of medicine in certain diseases. It must be remembered that there are patients who need operation and there are some who do not, and the outcome of this discussion should enable gynecologists to distinguish between these two classes. He is not prepared to take sides now; he desires to remain on neutral ground and to decide which patients need operation and which do not. Of course, if the physician does not operate, he must keep the patient under close observation. It seems to Dr. Craig that this is the safest course to pursue.

Dr. V. J. Hawkins, St. Paul, said that he has found fibroids accidentally during confinement ten times where one patient comes to his office for advice. It is not wise to advise every woman who has a fibroid to be operated on. He has had many patients operated on, and they are not well after the operation. If this operation should be performed in every case good results should be obtained in a large majority of the cases, and that has not been Dr. Hawkins' experience. Knowing this, and also that many of these patients get entirely well after menopause, the tumor disappearing, he stated that he can not agree with Dr. Eastman's views.

Dr. W. O. Henry, Omaha, Neb., said that it would be a great mistake to adopt the rule that all patients with fibroid should be operated on. Gynecologists have not yet reached the point in abdominal surgery where they can say that the operation is entirely safe. It is a great mistake to urge operation when the fibroid produces no symptoms, for there is always a possibility that the patient may succumb to the operation, no matter how skillful the operator. Some women have small fibroids, and when the menopause comes on the fibroid disappears. If the tumor does begin to make trouble there is sufficient warning, and then is the time to operate. Women in the child-bearing period have fibroids, and during the involution following pregnancy the tumor sometimes disappears. Each case should be studied individually and treated on its own merits. In reply to a question Dr. Henry said that when the fibroid degenerates there will follow hemorrhage or a profuse discharge of the some kind from the uterus; then there is time enough to operate and save the patient. He has not seen patients die, but has seen them recover after pregnancy with uterine fibroids.

Dr. R. T. Gilmore, Chicago, stated that hemorrhage as a symptom of the beginning of malignancy in fibroid tumors of the uterus is of questionable value, as hemorrhages frequently occur in small fibroids in which malignant changes can not be demonstrated. Hemorrhage especially aggravated at the menstrual periods is almost a constant symptom of simple fibroma.

Dr. C. L. Bonifield, Cincinnati, said that two years ago he reported five cases of pregnancy complicated by fibroids which seriously endangered the lives of the patients. One patient required a Cesarean section and two others Porro operations in order to save their lives.

THE AFTER-EFFECTS OF DIPHTHERIA ON THE HEART.*

FRANKLIN W. WHITE, M.D.
Physician to Out-Patients at the Boston City Hospital, Assistant in Theory and Practice of Physic, Harvard Medical School.
BOSTON.

It is well known that in diphtheria the heart muscle and the nerves which control it are the seat of certain changes which more or less seriously disturb its function, and the clinical signs of circulatory disturbance at the height of the disease and during convalescence have been carefully observed by many authorities. Much less is known, however, of the after-effects of the poison of diphtheria on the heart.

Veronese[1] says that lasting effects on the heart—except a moderate hypertrophy—do not follow diphtheria.

Romberg[2] has seen the mitral insufficiency present in convalescence in several cases last several months and then disappear.

Steffen[3] reports a case of mitral insufficiency following diphtheria which has been under observation for over four and a half years, and which he considers not a case of relative insufficiency, but of genuine valvular disease.

Baginsky[4] says that the disturbance of the heart in diphtheria even when not acutely threatening may be important by its persistence for months afterward. Occasionally a chronic myocarditis or mitral insufficiency may be left behind which does not indicate its presence by symptoms of failure of compensation until years later.

Schmaltz[5] has shown by a careful study of 81 cases of diphtheria with heart complications, that while diphtheritic myocarditis clears up in the majority of cases within a few months, in others it often persists after an attack of diphtheria for several years at least, and probably for life in some. The clinical picture is that of a mitral insufficiency with very few symptoms.

Jacobi[6] says that after severe epidemics of diphtheria cases of chronic heart diseases are frequent; some cases have arrhythmia and murmurs for life. The physical signs are irregularity of the heart, reduplication of sounds, especially the first sound, with extensive murmurs over the mitral or pulmonic areas and now and then increase of the transverse cardiac dullness. He states that this condition of the heart may be modified by a long period of absolute rest and proper hygiene, with the occasional use of cardiac stimulants.

Last year, in studying with Dr. H. H. Smith[7] the heart complications in nearly 1,000 cases of diphtheria treated at the south department of the Boston City Hospital, it was found that while severe heart complications are relatively infrequent, moderate disturbance of the heart is very common in diphtheria, as indicated by the great frequency of heart murmurs and a rapid or irregular pulse. It was found that these physical signs of a greater or less degree of cardiac disturbance were of long duration in many cases, making it desirable to watch the condition of the heart long after convalescence.

About one-third of these cases left the hospital after a stay of one or two months with a pulse rate of between 100 to 120 (*not including babies*), and in about one-third of the cases the heart was irregular at discharge.

In about three-fourths of the patients one or more murmurs were present at discharge from the hospital, which were considered in the majority of cases to be organic on account of their character, position and association with accentuation of the pulmonic second sound and irregular heart action. The condition is probably one of relative mitral insufficiency resulting from changes in the heart muscle.

The large number of children discharged from the hospital with a rather rapid and irregular pulse and cardiac murmurs is very striking, and contrasts strongly with the condition of children at the end of other acute infections, such as measles and scarlet fever, or the condition of adults at the end of such acute infections as typhoid, grip or pneumonia, and it seemed very desirable to keep a group of such children under observation until the heart had entirely regained its equilibrium or until the presence of permanent changes in the heart were evident.

This paper consists of a clinical study of 78 cases of diphtheria with heart complications after their discharge from the Boston City Hospital. The cases have been under observation *from five months to a year* to determine the frequency, importance and duration of subacute and chronic disease of the heart following diphtheria.

The cases were chosen from a large material as follows: 1.431 cases of diphtheria were treated at the south department of the Boston City Hospital in the last year with a mortality of 136 cases, or 9.57 per cent.[8] Thirty-three very severe cases survived their illness, and of this number 29 have been carefully followed since discharge from the hospital. These very severe cases, with few exceptions, had serious disturbances of the heart during their stay in the hospital, as indicated by gallop rhythm, marked irregularity, cardiac enlargement, murmurs, and rapid pulse; several had laryngeal stenosis requiring intubation; about one-fourth of the number had severe peripheral paralysis.

In addition, during the last quarter of the year 71 cases whose illness was of mild or of moderate severity left the hospital with well-marked signs of cardiac disturbance, such as enlargement, murmurs, or irregularity. Fifty-one of these patients have reported to me for observation several times a month; two cases of earlier date are also included in our series.

Of the 83 cases which have been carefully followed, 3 have been excluded on account of heart lesions which had developed before the attacks of diphtheria, and 2 ment. Is it at all probable that the death rate would have been so small had these patients, whose cases he quotes from McDonald's table, not been operated on as soon as the tumor was diagnosticated? Take the five cases of so-called harmless fibroids which I list out of a series of 169 cases. Would these patients not all have died without operations?

[8] If cases dying within twenty-four hours of their admission to the hospital are excluded, the mortality is 6.75 per cent.

It is a matter of curiosity as to what those operators who assume what Noble refers to as the classical or traditional attitude, do with other conditions in the abdominal cavity, conditions which are analogous in every respect to the so-called harmless fibroid. Recently I removed from a woman aged 73 an ovarian tumor weighing, with its contents, 30 pounds. She had carried this tumor for 25 years; she had never had any symptoms from it and was able to earn her own living. Would these classicists have allowed it to remain? They remove appendices in the interval, and small ovarian cysts; they remove symptomless gallstones from the gall bladder, not on account of any immediate danger, but on account of the fact that in no greater proportion than in fibromyomata of the uterus these various conditions will undergo changes threatening the life of the patient. For the same reason I remove all fibromyomata of the uterus.

In conclusion, considering the statistics, the accuracy of which can not be doubted, the low death rate in hysterectomy in the hands of competent operators and in cases not too long neglected, and particularly the fact that many of these tumors on removal reveal conditions threatening death, and which are not suspected, and can not be diagnosticated prior to operation, I am convinced that all fibromyomata should be removed unless there be concurrent conditions which render the operation inadvisable.

DISCUSSION.

Dr. Frank T. Andrews, Chicago, said that he is absolutely opposed to the position taken by Dr. Eastman, because it is so dangerous that it is vicious. He has seen many patients go by the menopause; in fact, it is his hope to carry them past the menopause and to watch them get well, and the vast majority do get symptomatically well. It is impossible to say in how many of Dr. Eastman's cases the tumors would have become cancerous if let alone. Few of these cases develop into sarcoma.

Dr. W. F. B. Wakefield, San Francisco, declared that he is absolutely in accord with everything Dr. Eastman said. His is true, up-to-date teaching.

Dr. J. H. Carstens, Detroit, asked in how many cases the growths undergo changes of various kinds, the result of interference with the circulation, and how many patients in a hundred will die if operated on. In his opinion more patients will undergo a change for the worse in the way of malignancy, septic conditions and adhesions if they are not operated on than would die if they were operated on. There is another thing to consider. A fibroid tumor is not appendicitis. An operation for fibroid ordinarily is not dangerous and one can select the time for operation. The patient can be put in such a condition that the operation will be almost free from any danger, and a man may be selected who is thoroughly competent to do the operation. The mortality will then be so small that the point made by Dr. Eastman is well taken. Every orthopedic surgeon operates on club feet, knock knees and deformities of all kinds in which the mortality is as great, and even greater, than it is in operations for fibroid. He operates for esthetic purposes or to restore lost functions, and the operation is justifiable. If the patient is young the tumor should be enucleated; if she is old the uterus and whatever else may be necessary should be removed. To let a woman go around with a tumor for ten or fifteen years is not good practice. It is the physician's duty to relieve the mental condition of that woman, to ease her mind and to make her mentally and physically comfortable. The patient, however, must be in good condition before an attempt is made to remove the fibroid.

Dr. L. H. Dunning, Indianapolis, agreed with Dr. Eastman in the main, but he would not like to be committed to the dictum that physicians should operate on every case of fibroid. It is true that 18 per cent. of fibroids undergo a dangerous degeneration, and, on the other hand, fibroid tumor operations—hysterectomy and myomectomy—do not, under favorable circumstances, give a mortality of more than 5 per cent.; that is to say, 13 per cent. is gained by the operative method. Many patients carry fibroids for fifteen or twenty years without any knowledge of the fact. They discover them accidentally when they are near the menopause. Many physicians have patients to show that 80 per cent. of fibroids undergo benign degeneration and absorption after the menopause. Given a woman 40 years of age, not suffering from the tumor, Dr. Dunning asked if gynecologists are not justified in assuring that woman that the probabilities are 80 per cent. in her favor that the tumor will disappear without harm to her. He would be exceedingly loth to undertake the removal of a tumor that produces no symptoms. If degeneration is taking place the signs are growth of the tumor, pain, fever, cachexia, increase of menstruation and painful menstruation. Dr. Dunning is of the opinion, based on considerable experience, that physicians are justified in many cases, especially when the patient is near the menopause, in watching the case, allowing the patient to go without operation when there are no symptoms. These patients, as a rule, take the matter cheerfully, and after the menopause their troubles gradually disappear.

Dr. D. H. Craig, Boston, stated that to propose the rule of operating in every case of fibroid is as much empiricism as is the administration of medicine in certain diseases. It must be remembered that there are patients who need operation and there are some who do not, and the outcome of this discussion should enable gynecologists to distinguish between these two classes. He is not prepared to take sides now; he desires to remain on neutral ground and to decide which patients need operation and which do not. Of course, if the physician does not operate, he must keep the patient under close observation. It seems to Dr. Craig that this is the safest course to pursue.

Dr. V. J. Hawkins, St. Paul, said that he has found fibroids accidentally during confinement ten times where one patient comes to his office for advice. It is not wise to advise every woman who has a fibroid to be operated on. He has had many patients operated on, and they are not well after the operation. If this operation should be performed in every case good results should be obtained in a large majority of the cases, and that has not been Dr. Hawkins' experience. Knowing this, and also that many of these patients get entirely well after menopause, the tumor disappearing, he stated that he can not agree with Dr. Eastman's views.

Dr. W. O. Henry, Omaha, Neb., said that it would be a great mistake to adopt the rule that all patients with fibroid should be operated on. Gynecologists have not yet reached the point in abdominal surgery where they can say that the operation is entirely safe. It is a great mistake to urge operation when the fibroid produces no symptoms, for there is always a possibility that the patient may succumb to the operation, no matter how skillful the operator. Some women have small fibroids, and when the menopause comes on the fibroid disappears. If the tumor does begin to make trouble there is sufficient warning, and then is the time to operate. Women in the child-bearing period have fibroids, and during the involution following pregnancy the tumor sometimes disappears. Each case should be studied individually and treated on its own merits. In reply to a question Dr. Henry said that when the fibroid degenerates there will follow hemorrhage or a profuse discharge of the some kind from the uterus; then there is time enough to operate and save the patient. He has not seen patients die, but has seen them recover after pregnancy with uterine fibroids.

Dr. R. T. Gilmore, Chicago, stated that hemorrhage as a symptom of the beginning of malignancy in fibroid tumors of the uterus is of questionable value, as hemorrhages frequently occur in small fibroids in which malignant changes can not be demonstrated. Hemorrhage especially aggravated at the menstrual periods is almost a constant symptom of simple fibroma.

Dr. C. L. Bonifield, Cincinnati, said that two years ago he reported five cases of pregnancy complicated by fibroids which seriously endangered the lives of the patients. One patient required a Cesarean section and two others Porro operations in order to save their lives.

THE AFTER-EFFECTS OF DIPHTHERIA ON THE HEART.*

FRANKLIN W. WHITE, M.D.
Physician to Out-Patients at the Boston City Hospital, Assistant in Theory and Practice of Physic, Harvard Medical School.
BOSTON.

It is well known that in diphtheria the heart muscle and the nerves which control it are the seat of certain changes which more or less seriously disturb its function, and the clinical signs of circulatory disturbance at the height of the disease and during convalescence have been carefully observed by many authorities. Much less is known, however, of the after-effects of the poison of diphtheria on the heart.

Veronese[1] says that lasting effects on the heart—except a moderate hypertrophy—do not follow diphtheria.

Romberg[2] has seen the mitral insufficiency present in convalescence in several cases last several months and then disappear.

Steffen[3] reports a case of mitral insufficiency following diphtheria which has been under observation for over four and a half years, and which he considers not a case of relative insufficiency, but of genuine valvular disease.

Baginsky[4] says that the disturbance of the heart in diphtheria even when not acutely threatening may be important by its persistence for months afterward. Occasionally a chronic myocarditis or mitral insufficiency may be left behind which does not indicate its presence by symptoms of failure of compensation until years later.

Schmaltz[5] has shown by a careful study of 81 cases of diphtheria with heart complications, that while diphtheritic myocarditis clears up in the majority of cases within a few months, in others it often persists after an attack of diphtheria for several years at least, and probably for life in some. The clinical picture is that of a mitral insufficiency with very few symptoms.

Jacobi[6] says that after severe epidemics of diphtheria cases of chronic heart diseases are frequent; some cases have arrhythmia and murmurs for life. The physical signs are irregularity of the heart, reduplication of sounds, especially the first sound, with extensive murmurs over the mitral or pulmonic areas and now and then increase of the transverse cardiac dullness. He states that this condition of the heart may be modified by a long period of absolute rest and proper hygiene, with the occasional use of cardiac stimulants.

Last year, in studying with Dr. H. H. Smith[7] the heart complications in nearly 1,000 cases of diphtheria treated at the south department of the Boston City Hospital, it was found that while severe heart complications are relatively infrequent, moderate disturbance of the heart is very common in diphtheria, as indicated by the great frequency of heart murmurs and a rapid or irregular pulse. It was found that these physical signs of a greater or less degree of cardiac disturbance were of long duration in many cases, making it desirable to watch the condition of the heart long after convalescence.

About one-third of these cases left the hospital after a stay of one or two months with a pulse rate of between 100 to 120 (not including babies), and in about one-third of the cases the heart was irregular at discharge.

In about three-fourths of the patients one or more murmurs were present at discharge from the hospital, which were considered in the majority of cases to be organic on account of their character, position and association with accentuation of the pulmonic second sound and irregular heart action. The condition is probably one of relative mitral insufficiency resulting from changes in the heart muscle.

The large number of children discharged from the hospital with a rather rapid and irregular pulse and cardiac murmurs is very striking, and contrasts strongly with the condition of children at the end of other acute infections, such as measles and scarlet fever, or the condition of adults at the end of such acute infections as typhoid, grip or pneumonia, and it seemed very desirable to keep a group of such children under observation until the heart had entirely regained its equilibrium or until the presence of permanent changes in the heart were evident.

This paper consists of a clinical study of 78 cases of diphtheria with heart complications after their discharge from the Boston City Hospital. The cases have been under observation from five months to a year to determine the frequency, importance and duration of subacute and chronic disease of the heart following diphtheria.

The cases were chosen from a large material as follows: 1.431 cases of diphtheria were treated at the south department of the Boston City Hospital in the last year with a mortality of 136 cases, or 9.57 per cent.[8] Thirty-three very severe cases survived their illness, and of this number 29 have been carefully followed since discharge from the hospital. These very severe cases, with few exceptions, had serious disturbances of the heart during their stay in the hospital, as indicated by gallop rhythm, marked irregularity, cardiac enlargement, murmurs, and rapid pulse; several had laryngeal stenosis requiring intubation; about one-fourth of the number had severe peripheral paralysis.

In addition, during the last quarter of the year 71 cases whose illness was of mild or of moderate severity left the hospital with well-marked signs of cardiac disturbance, such as enlargement, murmurs, or irregularity. Fifty-one of these patients have reported to me for observation several times a month; two cases of earlier date are also included in our series.

Of the 83 cases which have been carefully followed, 3 have been excluded on account of heart lesions which had developed before the attacks of diphtheria, and 2 cases are not considered because the time of observation has been too short.

[8] If cases dying within twenty-four hours of their admission to the hospital are excluded, the mortality is 6.75 per cent.

The 78 cases included in this paper consist of those in which there was no evidence of previous heart disease, and in which either the cardiac disturbance due to diphtheria has entirely cleared up or has been under observation for at least five months.

The patients' ages were as follows: None less than 1 year; 20 from 1 to 5; 33 from 5 to 10; 17 from 10 to 16; and 8 adults.

The sexes were about equally divided. Eight cases were mild, 42 moderately severe and 28 severe.

Most of the cases had murmurs, with more or less cardiac enlargement; about 20 were followed chiefly for other reasons, 5 because of persistent rapid heart action, 6 because of persistent irregularity, 4 because of early cardiac enlargement out of proportion to the other signs; also various severe cases without cardiac signs or symptoms were followed to see if any would develop later.

As shown by last year's paper, about 90 per cent. of diphtheria patients have some cardiac disturbance during their illness indicated by the development of murmurs, etc., but in one-quarter to one-half of the cases it is mild in type and of short duration, clearing up soon after the actual infection has passed and before the patients leave the hospital. In all the present cases it was more persistent and was evident when the patients went home.

Duration.—Sixty-five cases have become entirely well during observation as far as we are able to judge by the ordinary methods of examination; we have divided them into moderate and severe groups, and the following table shows fairly accurately the duration of the heart trouble, indicating the number of cases which had entirely cleared up during the intervals stated. The time is calculated from the onset of the attack of diphtheria.

	4th to 5th week.	6th to 10th week.	11th to 12th week.	15th to 20th week.	20th to 25th week.	25th to 30th week.	35th week.
Moderate ...	4	14	11	8	1	..	..
Severe	..	4	10	2	1	3	2
Total	4	18	21	10	2	3	2

In five cases the duration was not accurately determined, and 13 cases with cardiac lesions are still under observation.

The history of the majority of these cases is one of gradual disappearance of the cardiac signs extending over an interval of from two to four months. On the other hand, 20 patients, or about one-quarter of the whole number, still showed signs of cardiac disturbance at the end of four months' time, and of this number only six cleared up within the following two or three months.

Of the 13 cases with cardiac lesions at the present time, 5 have been under observation for five months, 4 for six months, 2 for eight months and 2 for eleven months. In some of these cases the cardiac lesions may clear up within the next year, in others I believe they may prove permanent.

It is evident that as a rule the patients with the most intense cardiac disturbance, those who have shown in the hospital marked irregularity of the heart, with gallop rhythm or reduplication, are the slowest to recover, taking four to six months or more.. This is not an invariable rule, however, as in one of the severest cases, in a child of 4, the only sign after leaving the hospital was a rapid pulse, which became entirely normal in two and one-half months after the onset of his illness. Five other children under 8 years of age whose hearts were seriously affected cleared up within the same time. On the other hand, among the patients having a mild attack of diphtheria is one child of 6 in whom irregularity of the heart persisted for five months.

CLINICAL HISTORY.

Before describing the clinical history of these patients in detail I wish to say a few words about the examination and function of the child's heart in health and disease in order to avoid confusion.

Especial care is needed in examining the hearts of children and interpreting the results because in health the physical signs, such as the size and position of the heart and its rate and rhythm vary much with the age of the child and because in heart disease the signs and symptoms are not altogether like those in adults.

We must keep in mind the normal condition at different ages in order to fully appreciate pathologic changes. The pulse in early life is not only more frequent but is very much more variable than in adults. The pulse may even be irregular in healthy infants.

The heart is somewhat higher and more horizontal than in adults, therefore the apex beat is higher and further to the left. The apex is outside of the nipple line until the fourth year; more than one centimeter to the left, however, is pathological. From the fourth to the ninth year the apex is in or near the nipple line; after the thirteenth year it is invariably within the nipple line. From the end of the first year to the sixth year the relative cardiac dullness extends one or one and a half cm. to the left of the nipple line, and nearly to the parasternal line on the right side. From 6 to 12 years of age the left border is at or very near the nipple line and the right border between the sternal and parasternal lines. Any considerable deformity of the chest wall, such as is often found in rachitis, changes somewhat the heart's position in relation to it.

Functional murmurs are very much less common in children than in adults, and many competent observers deny their existence in the earlier years. The child's heart has greater powers of recuperation, and acquired heart disease runs a relatively favorable and mild course, the subjective symptoms are fewer, passive congestion is much less intense, and compensation is much more readily acquired.

I shall say very little about the condition of these patients during their stay at the hospital, having fully described the clinical history of a much larger number of cases in the paper already referred to. The signs of cardiac disturbance developed usually within the first week or two of the diphtheria and persisted during and after their discharge from the hospital; the milder cases remained in the wards about one month, cases of moderate severity from one to two months, and the severe cases, as a rule, from two to three months. Three cases stayed over three months.

AVERAGE TYPE.

We will consider first the average type. With few exceptions the general condition of these patients was good when they reported to me after leaving the hospital and symptoms of heart trouble were conspicuous by their absence. The discrepancy between symptoms and physical signs was often very striking. The children usually returned to school within a month after leaving the hospital, took a moderate amount of exercise, and often felt entirely well. At most there was slight complaint of palpitation or short breath after active exercise.

It is not fair, however, to measure the character of the case by the symptoms or to conclude that the heart trouble is trifling because few symptoms appear. In spite of the scarcity of symptoms the presence of a heart lesion was plainly shown by a variety of physical signs.

One important physical sign was cardiac enlargement, usually accompanied by a systolic murmur at the mitral area and an accented pulmonic second sound. It was present in 31 cases, comprising most of those of long duration. It was not found in those which cleared up within a few weeks after their discharge from the hospital. It was undoubtedly due largely to dilation of the heart, and was usually much more apparent when the child reported a week or more after leaving the hospital than at the time of discharge, evidently showing that the child had been too active after leaving the quiet wards and the heart had not been equal to the strain.

The increase in the area of relative cardiac dullness was usually more to the left than right, and at its height the left border was one to two cm. and the right border one-half to one cm. further out than normal for the age. The apex beat was about one cm. further to the left than normal. This large cardiac area lessened gradually, month by month, till within normal limits, in the cases which recovered.

The most frequent sign was the presence of murmurs; they were found after discharge from the hospital in all but 17 of the cases. They were always systolic in time; were heard most frequently over the mitral area, less often over the whole precordia, were frequently transmitted to the axilla and usually accompanied by an accentuated pulmonic second sound. They were usually blowing in character, but were musical or alternately musical and blowing in about 10 per cent. of the cases. They were usually increased by muscular exertion.

In 35 cases the murmurs indicated by their position, character, transmission and association with cardiac enlargement and accented pulmonic second sound, the presence of a relative mitral insufficiency, or possibly in exceptional cases of a mitral endocarditis. In a few older children and adults, however, with normal, regular pulse and a heart of normal size, a systolic murmur was heard at the base of the heart, which was sometimes affected by respiration and change of position of the patient. These murmurs disappeared with improvement of the patient's general condition and were considered to be probably haemic murmurs. There seems little danger of confusing haemic with organic murmurs in this investigation, because of the rarity of haemic murmurs in children and the lack of anemia in these cases.

The pulse was usually a little more rapid than normal, and in 5 cases a rapid heart action was the only sign of importance. Irregularity of the pulse was frequently met with in the first few weeks after leaving the hospital. In eight cases the irregular action was the only striking sign of heart trouble.

It seemed wise to advise a quiet life in the presence of definite cardiac disturbance, but it was often difficult to control the patients, and a considerable number attended school and took moderate exercise while cardiac murmurs and irregularity were present, without any symptoms or perceptible bad results.

It is impossible to determine in individual cases the anatomical cause of these clinical signs, but it is doubtless a faulty closure of the mitral valves, due chiefly to dilatation of the valvular ring or imperfect function of the papillary muscles, and only in an occasional rare case to a mitral endocarditis.

Autopsies have shown the rarity of endocarditis in diphtheria, and the clinical fact that the majority of the cases apparently recover speaks against frequent injury to the valves.

The following condensed histories illustrate the course of the disease in cases of moderate severity. Cases 32, 49, 53, 70 and 77 are typical patients, with murmurs and cardiac enlargement of moderate duration. Case 42 is a type of the persistently rapid heart without other signs, and Case 7 of the persistently irregular heart.

Case 7.—Girl, 6 years, mild diphtheria. First week: Pulse regular, 95, normal. Third week: Left hospital; pulse slightly irregular, 95; heart normal size, blowing systolic murmur over mitral area not transmitted; pulmonic second not accentuated; no symptoms. Remained at home one month; since then in school; slight irregularity persisted for nineteen weeks; absent at the end of twenty weeks.

Case 32.—Girl, 6 years; moderately severe case. First week: Pulse irregular and rapid (100 to 160); heart normal size; soft systolic murmur at apex, not transmitted; pulmonic second accentuated. Eighth week: Left hospital; pulse regular, 115; heart same; slight debility after diphtheria; not sent to school. Twelfth to sixteenth week: Pulse regular, 100; heart dullness from 2½ cm. outside of left nipple line to right parasternal line; no murmurs. No symptoms. Twenty-second week: Pulse regular, 86; heart normal size; no murmurs.

Case 42.—Boy, 11½ years; moderate case of diphtheria, followed by palatal paralysis; in bed four weeks. Fourth week: Pulse regular, 100; heart normal. Eighth week: Left hospital; pulse regular, 110; heart normal in size without murmurs. Thirteenth week: Pulse became normal after being persistently rapid (110) and slightly irregular at times; heart normal.

Case 49.—Girl, 5 years; moderate case. First week: Pulse regular, 95; heart normal. Third week: Left hospital; pulse regular, 95; heart normal size; soft systolic murmur over mitral and pulmonic areas, not transmitted; pulmonic second sound slightly accentuated. Fourth week: Slight paralysis of legs. Sixth week: Pulse regular, 80; heart dullness from 2½ cm. outside of left nipple line to right parasternal line; apex beat ½ cm. outside of nipple line in fourth interspace; musical systolic murmur over mitral area, transmitted to axilla and base; pulmonic second sound accentuated; child was found to become tired and pale after moderate exertion; symptoms disappeared with a few weeks' rest. Sixteenth week: Left border of the heart dullness was only 1 cm. outside of the nipple line; the musical murmur persisted. Case still under observation.

Case 53.—Girl, 12 years; moderately severe case. Second week: Pulse regular, 90; heart normal. Fourth week: Left hospital; pulse regular, 100; heart dullness from ½ cm. outside of left nipple line to right sternal edge; soft systolic murmur loudest over mitral area; heard also over pulmonic area. Ninth week: Pulse regular, 96; heart dullness from 2 cm. outside of left nipple line to 1 cm. beyond right sternal edge; apex beat fifth space just outside of nipple line; murmur continued same. Fourteenth week: Pulse normal; heart normal in size; soft systolic murmur was heard at base only after exercise and with the patient lying down.

Case 70.—Girl, 10 years; moderate severity. Second week: Slight laryngeal stenosis, not intubed; pulse regular, 100; heart normal size, blowing systolic mumur at apex, not transmitted. Eighth week: Left hospital; pulse regular, 92; heart normal size; blowing systolic murmur over mitral and pulmonic areas, slightly transmitted. Tenth week: Pulse 100, irregular on exertion; heart dullness from 2 cm. outside of left nipple line to 1 cm. beyond right sternal edge; apex beat fifth space just outside nipple line; murmurs continue same; pulmonic second sound accentuated. Sixteenth week: Pulse same; heart same except that murmur at base of heart has disappeared; no symptoms; case still under observation.

Case 77.—Woman, 26 years; moderately severe case; in bed ten days. First week: Pulse regular, 110; heart normal size; blowing systolic murmur over entire precordia, loudest at apex, transmitted slightly to axilla; pulmonic second accentuated. Second week: Left hospital; pulse regular, 108; heart normal size; systolic murmur at apex, slightly transmitted. Third week: Pulse regular, 100; heart dullness from 1 cm. outside of left nipple line to 1 cm. beyond right sternal edge; apex beat fifth space in nipple line; murmur same; no symptoms save slight debility. Fifth week: Pulse regular, 80; heart normal size; no murmurs.

SEVERE TYPE.

The severe cases were usually kept in bed from 4 to 8 weeks, and did not leave the hospital until the end of the second or third month. The symptoms of heart trouble were more evident and were striking in occasional instances. Palpitation was frequently complained of, in others the mother noticed weakness, pallor and faintness after exertion; one or two older children complained of cardiac distress.

These symptoms were most pronounced in the first few months after leaving the hospital and gradually disappeared. In several cases the attacks of palpitation and rapid pulse after slight exertion persisted for more than six months. Where these symptoms were at all prominent a very quiet life was advised with intervals of rest in bed. There was no cyanosis or edema.

As in the milder cases cardiac enlargement was present in most of the cases of long duration, it was not common while the patients were in the hospital, but showed itself after their return home, and was undoubtedly due to cardiac dilatation from over exertion. The increase in the area of cardiac dullness was similar to that found in the milder cases, but was usually much more persistent. The murmurs were similar in character; the first sound at the apex was normal or slightly enfeebled, late reduplication of the first sound was occasionally met with and in one case has persisted for ten months.

The pulse was usually considerably more rapid than normal and was easily increased from 30 to 40 beats by slight exertion.

Irregularity of the pulse was frequently met with, and in many instances persisted for months; this was also increased by any exertion.

The following cases which have been under observation for from six months to a year illustrate the course of the disease in severe infections. Cases 17 and 33 are typical ones of moderately long duration, one having cleared up at the end of nine months and one being still under observation. Case 48 is an example of persistent reduplication of the first sound with enlargement, Cases 9 and 51 of persistently rapid hearts, and Case 13 of a persistent irregularity of the heart.

Case 9.—Boy, 14 years; very severe case; in bed five weeks. First week: Pulse persistently irregular and rapid, 120; heart dullness from 1 cm. outside left nipple line to right sternal edge; no murmur. Eighth week: Left hospital; pulse slightly irregular, 110; heart dullness from 1 cm. outside left nipple line to right sternal edge; no murmur. Heart remained rapid for two months after discharge; only symptom dyspnea after active exertion; did not go to school for five months. Twenty-third week: Pulse regular, 100, not especially increased on exertion; heart normal size; no murmur.

Case 13.—Girl, 7 years; very severe case; in bed four weeks. Second week: Pulse, marked irregularity, 100 to 130; heart dullness from 1½ cm. beyond left nipple line to right parasternal line; no murmurs. Sixth week: Left hospital; no symptoms except those of moderate debility; pulse irregular, 100; heart normal size; no murmurs. Tenth week: Heart irregularity has gradually disappeared.

Case 17.—Girl 7, years; very severe case; temperature 101 to 103 for three weeks; in bed seven weeks; occasional attacks of blueness and pallor. Second week: Pulse irregular, 120 to 140; heart dullness from 1 cm. outside left nipple to right sternal edge; no murmurs; reduplication of first sound. Ninth week: Left hospital; paralysis of legs one month; pulse irregular, 120; heart normal size; no murmurs. Eighteenth week: Pulse irregular, 84; became more irregular and 108 after very slight exertion; heart dullness from 1½ cm. outside left nipple line to right costal edge; first sound weak; second aortic sharper than second pulmonic sound; systolic murmur at base and apex, loudest at base, slightly transmitted to axilla; no symptoms. Twenty-sixth week: Pulse weak, regular, 80 to 100; heart dullness from 1 cm. outside left nipple line to right costal edge; apex just outside nipple line; murmurs same; heart action stronger; no cardiac symptoms. Forty-second week: Pulse regular, 88; heart dullness from 1½ cm. outside left nipple line to right parasternal line; apex 1 cm. outside nipple line; systolic murmur at apex and base, loudest at apex; slightly transmitted to axilla, increased by exertion; pulmonic second sound accentuated; no symptoms; general condition good; case still under observation.

Case 33.—Boy, 5 years; very severe case; in bed seven weeks. Second week: Pulse irregular, 110 to 130; heart normal size, no murmur; reduplication of first sound and gallop rhythm. Thirteenth week: Left hospital; paralysis of palate and legs; pulse regular, 105; heart normal size, slightly musical systolic murmur at apex slightly transmitted; pulmonic second accentuated. Thirty-third week: Pulse regular, 80; heart became slightly enlarged; now normal size; musical systolic murmur at apex slightly transmitted; pulmonic second accentuated; no symptoms. Thirty-fifth week: Pulse regular, 80; heart normal size; no murmurs.

Case 48.—Boy, 7 years; very severe case; in bed seven weeks. First week: Pulse irregular, 120; heart normal size; persistent reduplication of first sound; blowing systolic murmur at apex, not transmitted. Eighth week: Left hospital; pulse irregular, 100; heart normal size; occasional marked reduplication of first sound; systolic murmur at apex not transmitted; pulmonic second slightly accentuated. Thirty-seventh week: Murmurs have slowly disappeared; heart has notably enlarged; no cardiac symptoms; pulse regular, 80; heart dullness from 3 cm. outside left nipple line to right parasternal line; constant reduplication of first sound at apex; entered school six weeks after leaving hospital; case still under observation.

Case 51.—Man, 28 years; moderately severe case. First week: Pulse regular, 80; heart normal size; soft systolic murmur at apex and base, loudest at apex; pulmonic second sound accentuated. Second week: Pulse irregular and rapid (120), after very slight exertion; heart same. Fourth week: Syncope after slight exertion; pulse irregular and intermittent; occasional attacks of violent palpitation with cold sweat; heart normal size, no murmurs; kept in bed for one month. Fourteenth week: Heart still rapid, 110 to 120, after slight exertion; otherwise normal. Twentieth week: General condition good; returned to work. One year: For past six months heart becomes rapid, 120, after even moderate exertion; this condition gradually improving; no other cardiac symptoms or signs.

PROGNOSIS.

We find that in a large number of cases the cardiac disturbance after diphtheria soon clears up, but that in a considerable number it lasts a long time. In thirteen cases, or about 17 per cent. of the number studied, the heart trouble is now present after the end of five or six months, the longest cases now under observation being two for eight months and two for eleven months.

We have seen several cases in which the cardiac disturbance has lasted seven and nine months entirely clear up. Schmaltz has seen this happen in quite a number of cases after one or even two years' duration, which shows that it is not necessary to give up hope of recovery in individual long cases.

We have seen that the duration of the heart trouble is usually in proportion to the severity of the original illness, but this is not always the case. Occasionally a quick recovery follows a severe illness, and sometimes disturbance of the heart persists for many months after a mild diphtheria.

Schmaltz cites a few cases in which heart disease developed after normal convalescence and first showed itself one or two months after the attack of diphtheria; we have not found any such cases of late development.

The fact that most children have few or any heart symptoms after diphtheria must not mislead us as to its real effect on the heart. In childhood the heart has great reserve force and it is capable of doing good work even under very unfavorable circumstances.

TREATMENT.

The after-treatment consists in a sufficient period of rest in bed, and then in watching the effect of mild exercise on the heart, for several months at least, and grading it to meet individual requirements. Tonic drugs, such as strychnia and iron, are occasionally useful.

How rigidly the rest cure must be enforced depends entirely on the individual case. We found last year in our study of cases in the hospital that it was not necessary to keep all patients in bed who had cardiac murmurs and a pulse which was slightly irregular and somewhat increased in rate. After four or five weeks of rest in bed the cases of moderate severity experienced no ill effects from being allowed to sit up for short and progressively longer intervals if the heart was carefully watched; frequently the heart's action seemed to be improved by this change.

We have also seen that many mild cases after leaving the hospital with murmurs and slight cardiac enlargement and irregularity became entirely well in a month or two without special care. I believe it would be a mistake to invariably keep these children at home and put them to bed, but over exertion should be carefully guarded against.

I have no doubt that much of the cardiac dilatation which was often seen in the first few weeks after leaving the hospital could have been avoided by more intelligent restraint of these children at home. Even the milder cases should be carefully watched and whatever causes shortness of breath, pallor or fatigue, or affects the heart unfavorably by notably increasing the pulse rate, causing irregularity or any increase in the cardiac area should at once be stopped, whether it consists of running, walking, playing or even in simply being out of bed. The heart must be given abundant opportunity to rest and recover its normal function. This is the only conservative treatment and the only way to avoid permanent damage to the heart in some instances.

All the severe cases require rest in bed and careful watching of the heart for months or years afterward.

CONCLUSION.

1. The cardiac disturbance after diphtheria usually presents the picture of a mitral insufficiency with irregular heart action and few symptoms. Occasional cases have rapid pulse or cardiac irregularity without any other signs.

2. Moderate disturbance of the heart is very common after diphtheria and in a large number of cases persists from two to six months after the original illness.

3. In many cases the cardiac lesion does not clear up in the first half year, but lasts much longer; some ultimately recover; others probably do not. The duration of the heart trouble is usually in proportion to the severity of the original illness.

4. The fact that children often have few heart symptoms after diphtheria must not mislead us as to the importance of the injury to the heart.

5. Cardiac disturbance of long duration following diphtheria may be entirely recovered from. It is not necessary to give up hope of recovery in individual long cases.

6. The treatment of this condition consists in a sufficient period of rest in bed, and then in watching the effects of mild exercise on the heart for several months at least and grading it to meet individual requirements.

This paper is called a preliminary report because it is very desirable to keep those patients who still have heart lesions under observation for several years, and every effort will be made to do this.

In closing, I wish to thank Dr. J. H. McCullum, medical director of the south department of the Boston City Hospital, and Dr. A. E. Steele, assistant resident physician, for their hearty co-operation; also Dr. J. L. Morse and Dr. H. H. Smith for notes on two cases.

DISCUSSION.

Dr. G. R. Campbell, Augusta, Maine, declared that the thing which impressed him strongly was the necessity of rest after diphtheria as a preventative treatment for the after effects on the heart. Many physicians are apt to consider their diphtheria patients entirely recovered as soon as the throat is cleared and the patient able to sit up. The action of the heart after moderate exercise, simply the rapid action of the heart, should be a warning that the heart muscle has not resumed its normal tone. If these patients were put to bed as soon as rapid action after moderate exercise is noted Dr. Campbell thinks physicians would be enabled to prevent many of the dangerous after effects of this disease on the heart.

Dr. H. M. McClanahan, Omaha, Neb., said that since the introduction of antitoxin the number of heart lesions following diphtheria has seemed to increase. Among the laity he is frequently asked whether there is any danger in using the antitoxin; he would say not, and yet there is a feeling fostered by some members of the profession that antitoxin is a dangerous remedy. It is not understood that diphtheria is dangerous to the heart. Antitoxin is an excellent remedy, but physicians can not guarantee that it will undo the injury done by the toxins of diphtheria. The time of its administration is an important element. Dr. McClanahan has found that within the last two years the prejudice has grown because of the statements that it is injurious to the heart. After the throat has cleared up the patient is too often considered practically well; this is not true. The danger to the heart should be watched and great care taken to keep the child quiet in bed until the pulse has resumed its normal rate. The child should then be carefully watched to note the effect exercise has on the heart muscles.

Dr. W. J. Butler, Chicago, said that the deleterious effects of diphtheria on the heart are to a considerable extent in proportion to the delay in administering antitoxin. Patients receiving antitoxin within the first forty-eight hours seldom show any after effects on the heart. Cases in which it is administered at a later period after the diphtheria has exerted its full effect on the heart may show very positive disturbances that may be of a fatal character. The value of the systolic murmur as indicative of mitral insufficiency, he thinks is slightly overrated in these cases. In almost any of the severe acute infections there may be systolic murmurs over the heart without any organic lesion, either relative or acquired; in other words, accidental murmurs. A heart so affected permit of the occurrence of a relative insufficiency will be accompanied with the most profound symptoms of incompensation. The systolic murmur *per se*, whether heard at the apex or base, can hardly be regarded as of positive diagnostic value. In some cases in which the heart is quite widely dilated and one would have every reason to suspect a mitral insufficiency, there will be absolutely no murmur. On the other hand, a heart not enlarged may give a systolic murmur over the apex or base; likewise, an accentuated second sound. Pulse irregularity, both in quality rhythm and rate, and dilatation of heart, are certainly the most important physical points in determining the deleterious effects of the diphtheria toxins on the heart.

Dr. Arthur W. Fairbanks, Boston, thinks there is no doubt but that the cases of heart lesion following diphtheria have seemed to increase since the use of antitoxin, but he believes the chief factor in the increase is the fact that so many patients who had had a very severe type of diphtheria are now living. Formerly such patients died during the diphtheria. That the children get up too soon is a very important point; the fault lies not with the parent alone, but with the family physician. Dr. Fairbanks has frequently seen children up and out of bed in a couple of days after the diphtheria. The clearing of the throat has been taken as a sign by the parents that the child should be allowed to get up, and the family physician is only too ready to yield to the importunity of the parent. Fortunately, through the quarantine laws, some of these children are kept in a room for a good many days after they are apparently well. This is a blessing to the children. Dr. Fairbanks recently saw a child seven months after discharge from the hospital. The child was 10 years old and she had a pure dilatation of the heart with marked subjective signs of muscular incompetency. She was put to bed and the heart came down and there was then no souffle, showing that the heart dilatation was not due to an organic lesion, but to myocarditis. The child was seen two weeks after getting up and was found to be in good condition, and there have been no subjective symptoms since. He thinks the occurrence of the souffle after the fever as a rule is an indication of mitral insufficiency. During the acute stage of the diphtheria he does not think it can be so interpreted. In many cases he thinks this insufficiency is only a relative one. In this country physicians have not considered sufficiently the method of Schott for the treatment of heart disease. Dr. Fairbanks believes that the baths, the resisted muscular movements and massage are of value in these cases of muscular insufficiency of the heart.

Dr. C. F. Wahrer, Fort Madison, Iowa, stated that when patients of this kind are first seen inquiries should be made regarding the previous diseases the child has had. The heart lesion is often found to be secondary to some other process. He suggested that at the next meeting some one read a paper on heart diseases of primary and secondary character. He mentioned one case showing the importance of rest after diphtheria. Four children in a family had diphtheria. The first was apparently making a good recovery, and he instructed the parents not to allow this child to make any exertion; that she needed to be at rest, kept in a horizontal position. They did this for about ten days. He called occasionally at the house to see the other children. One morning, while the parents were at breakfast, the child was lying in bed when she noticed that micturition started. She called to her parents in a startled tone, and when they reached her she was sitting on the commode, dead. This case was undoubtedly one of muscular failure, dependent on degeneration changes from the diphtheretic intoxication. Dr. Wahrer emphasized the point brought out by Dr. Fairbanks relative to the apparent increase of heart disease after the use of antitoxin. That increase is only apparent, and it is similar to the apparent increase in the number of surgical operations.

Dr. H. E. Garrison, Dixon, Ill., said that nothing has been said concerning the diet in diphtheria. In one case which she had under observation before antitoxin came into use she kept the child perfectly quiet in bed. The throat had cleared up and the child seemed to be perfectly well. The grandmother concluded that she needed something to eat and she gave her hard-boiled eggs. The next day when Dr. Garrison saw her the pulse was very rapid and that night she died. Dr. Garrison thinks that it is necessary to emphasize the kind of diet needed and to keep these patients on a light diet for several days after the subsidence of the disease.

Dr. Kate Lindsay, Boulder, Colo., emphasized the importance of Dr. Garrisons remarks concerning the necessity of careful dietary. Dr. Lindsay had two cases which illustrate the subject. One was a case of heart lesion before the use of antitoxin and one after. Physicians emphasize the importance of physical rest and make that all-important in all cases of heart lesions. A child may be kept physically still, and yet if subjected to nervous excitement the results may be quite as bad. The question in Dr. Wahrer's case might be raised whether the child died of nervous shock or as the result of the muscular exertion. The treatment in any disease in which the heart is injured is a broad subject and as yet has not been sufficiently studied.

Dr. William J. Butler, Chicago, does not believe that physicians can accept the presence of a systolic murmur following diphtheria as an evidence of cardiac disease. These cases sometimes continue for months with a systolic murmur, which is apparently considered a sign of relative insufficiency. Mitral insufficiency of relative character presupposes a considerable dilatation of the heart. A systolic murmur alone does not indicate relative insufficiency. It is a common thing to find these accidental murmurs in children who had not previously had an acute infection of any kind. He emphasized the fact that the presence of a systolic murmur *per se* following diphtheria can not be accepted as an evidence of cardiac disease unless there is a very marked dilatation of the heart, especially of the left ventricle.

Dr. John Lovett Morse, Boston, did not agree with Dr. White that functional murmurs in the heart were rare in childhood. Dr. Morse thinks that they are very common in childhood.

IMMUNITY.

CHAPTER XXVIII.

TUBERCULOSIS AND PSEUDOTUBERCULOSIS IN ANIMALS.

Bovine Tuberculosis.

Certain differences between the bacilli of human and bovine tuberculosis were mentioned in the preceding chapter. In cattle the disease shows a characteristic tendency to remain localized in one organ or group of organs over a long period. It is a nodular disease as in man, but differs from human tuberculosis in that the nodules often grow to large size, may be imbedded in and sharply differentiated from surrounding healthy tissue, and not infrequently involve serous surfaces, forming large masses of firm sessile or pedunculated tumors. The nodules frequently are fibrous from the beginning, undergo early and extensive calcification and rarely soften. We are not to understand, however, that miliary tuberculosis does not occur in cattle. Although the process in the lungs is usually of a fibrous and large nodular nature, rapid dissemination with formation of many miliary tubercles may cause the picture of acute tuberculous consolidation in a certain number of cases. According to the statistics of Ostertag, based on 43,000 cases of bovine tuberculosis, localization is as follows: Lungs, 75 per cent.; pleura and peritoneum, 50 per cent.; peribronchial glands, 60 per cent.; spleen, 40 per cent. In more or less generalized cases the lungs are involved in 100 per cent. of the cases; serous membranes, 90 per cent.; liver, 85 per cent.; digestive tract, 60 per cent.; spleen, 50 per cent.; kidneys, 30 per cent.; mouth cavity, 5 per cent. In cows the uterus, in general infection, is involved in 65 per cent. of the cases, the udders in from 5 to 10 per cent., and the ovaries in 5 per cent. It seems that the lungs are the most common infection atrium, and transmission probably is accomplished chiefly through the secretions of the respiratory passages. In the udders the process may at first be one of miliary tuberculosis, but a large amount of fibrous tissue forms in time, many acini are transformed into retention cysts, in which tubercle bacilli, free or intracellular, may be present in large numbers.

Aside from anatomic changes and clinical symptoms, diagnosis depends on the tuberculin reaction, and, in relation to the udder, the demonstration of bacilli in the milk by staining methods or inoculation into guinea-pigs.

The tuberculin reaction in cattle is similar to that in man and is subject to the same general limitations, but is used extensively with the most satisfactory results. The complete elimination of tuberculosis from herds of cattle is possible, by using tuberculin as a diagnostic test, the slaughtering of infected animals, and the disinfection of stalls.

Tuberculosis among sheep and goats is rare. It occurs occasionally in the horse, hog and dog, and with more frequency in the cat.

Avian Tuberculosis.

A form of tuberculosis is very common in the chicken, and attacks also the pheasant, dove and turkey. The duck and goose are exempt from it. Although the organism resembles that of human tuberculosis in size, staining properties and other general characteristics, differentiation is accomplished by means of the following points: 1. The avian bacillus shows a greater tendency to pleomorphinism as shown by club-shaped forms, unstained vacuoles, "spore-like" bodies, and branching threads. 2. It has a greater affinity for aqueous anilin dyes. 3. Growth takes place in artificial media more rapidly and on solid surfaces is characterized by its moist appearance and mucus-like consistence in contrast to the dry, warty, brittle growth of the human bacillus. 4. The optimum temperature for growth (from 40 to 45 C.) is several degrees higher than that of the mammalian organism. 5. Its pathogenicity for guinea-pigs is less and for rabbits greater than that of the human and bovine bacilli. Their difference in pathogenicity is further shown by the difficulty which is met in trying to infect fowls with the human bacillus. By varying the conditions of cultivation and by animal passage the two may be made to resemble each other very closely, although the permanent transformation of the human into the avian, or vice versa, has not been accomplished.

The disease attacks especially the intestines, mesentery and liver, in which are found hard, yellowish-white nodules, often rich in lime salts, and varying in size from that of a pea to that of a walnut. These conditions suggest the intestines as the infection atrium. The foci are rich in bacilli and histologically show the essential characteristics of tuberculosis.

Tuberculosis of Fish, Etc.

"*Bacillus tuberculosis piscium*" is the name given to an acid-fast organism resembling the tubercle bacillus which was cultivated from an inflammatory tumor in the abdominal wall of a carp. It grows well at low temperature, the optimum being 25 C., is found in large numbers in the lesions within giant cells, and is distinctly pathogenic for frogs. Certain authors state that the human bacillus when inoculated into the frog undergoes changes in its cultural and pathogenic characteristics, eventually resembling the organism cultivated from fish.

Similar bacilli have been cultivated from a form of tuberculosis in the turtle (Friedman), and *Blindschleiche*—blind worm (Moeller).

Other Related Organisms.

Certain other organisms of low pathogenicity resemble the tubercle bacillus in their acid-fast properties, their ability to grow in the form of branching threads, and to produce tubercular or nodular infections of a local nature in animals. They may be placed in a group which includes the tubercle bacillus.

C. Fraenkel, also Neufel, recognize in smegma two acid-fast bacilli, calling one "tuberculoid" because of its morphologic resemblance to the tubercle bacillus, and the other "diphtheroid" since it shows the pleomorphism of the diphtheria bacillus. One of these organisms may be identical with the "syphilis bacillus" (?) of Lustgarten. Smegma bacilli are most numerous beneath the prepuce in man and about the clitoris and vulva in women. Their chief significance lies in the danger that they may be mistaken for tubercle bacilli in suspected cases of genitourinary tuberculosis. Smegma bacilli may readily enter the urethra in women and be carried into the bladder during catheterization or cystoscopic examination. In man the danger of bacteriologic error may be eliminated largely by cleansing the glans and carefully irrigating the urethra. Urine which is then passed is not likely to contain smegma bacilli (Young and Churchman).

"Milk bacilli" and "butter bacilli" are acid-fast organisms resembling the tubercle bacillus morphologically. In injecting milk into guinea-pigs as a test for tuberculous milk, Petri occasionally noted, as a consequence, a thick membranous growth which encased the liver and spleen and bound the coils of intestines together. The omentum was thickened, and this structure and the mesenteric lymph glands contained nodules. In pure culture the organism is pathogenic for guinea-pigs only when given in large doses, and may kill the animals in several weeks with the anatomic changes noted above. Its virulence is increased by the simultaneous injection of butter. It is not pathogenic for man (Herbert).

Moeller cultivated organisms resembling the tubercle bacillus from timothy (timothy bacillus), from manure, and a third (grass bacillus II) from the dust of a manger. The last is marked by great pleomorphism, thread formation and motility in young cultures.

Pseudo-tuberculosis in Animals.

Although some of the organisms described above are often called pseudotubercle bacilli, the term pseudotuberculosis is now applied somewhat specifically to a nodular disease occurring in rats, mice and sheep (and perhaps in other domesticated animals), and in which organisms differing from the tubercle bacillus in staining and culture properties, morphology and pathogenicity, are found. The clinical course and anatomic changes are similar in the three animals mentioned, although the organisms are different. The lymph glands near the infection atrium become enlarged chiefly by a cellular infiltrate rather than extensive proliferation of fibrous tissue. The nodules undergo a soft caseation very early and rarely show calcification. The infection finds its way to other sets of lymph glands and may become more or less generalized with the formation of smaller and larger sized nodules.

Rats and Mice.

Pseudotuberculosis of rodents, occurring spontaneously in rats, guinea-pigs, rabbits, cats and also chickens, is caused by an organism of considerable pathogenicity, and may occur in epidemic form in laboratory animals. Intraperitoneal inoculations in guinea-pigs are fatal in a few days. Spontaneous infection takes place through the intestinal tract, and the regional organs show the principal changes. The liver and spleen contain many nodules which may be as large as a hazelnut, and which are frequently caseated in the center. The organism is called *Bacillus pseudotuberculosis rodentium* or *Streptobacillus pseudotuberculosis dor*.

The disease in mice is caused by a diphtheria-like organism called *Bacillus pseudotuberculosis murium* and is pathogenic especially for the gray mouse.

Sheep.

A similar infection in sheep is of more importance and occurs with some frequency. It is called pseudotuberculosis ovis, and the bacillus has a corresponding name. The organism is supposed to gain entrance through wounds in the feet and legs, following which the adjacent lymph glands become involved, and the infection may be transferred to the lungs and other organs through the lymphatic circulation. The lesions are nodular, of varying size, usually surrounded by a fibrous capsule, and are either semipurulent or undergo early caseation. They may be found in all the visceral organs.

An organism resembling that cultivated from the sheep has occasionally been found in nodular conditions in cattle.

The leprosy bacillus and the bacillus of Lustgarten, organisms which resemble the tubercle bacillus, will be considered later.

Falling of Hair After Erysipelas.—After cutting the hair short, Shoemaker uses the galvanic alternated with the faradic current every day or two, and singes the hair ends every two or three weeks. He also applies equal parts of oil of ergot and fluid mercury oleate.—*Denver Med. Times*.

THE NATURE OF PUERPERAL ECLAMPSIA.

Since Jürgens in 1884 described the peculiar changes in the liver in puerperal eclampsia, a large number of carefully studied cases has accumulated, so that it may be said that the pathologic anatomy of the disease now is fairly well understood. Perhaps the most active observer in this field has been Schmorl in Dresden, who has studied no less than 73 cases.

Harbitz, who recently reviewed all this work, points out that the most important, essential, anatomic changes in eclampsia concern the blood, in which there is more or less laking of the corpuscles and coagulation with the formation of thrombi and emboli; associated with and partly, at least, dependent on these alterations are hemorrhages, infarctions and necroses. The liver of eclampsia, with the congestion, infarctions and degenerations, presents a picture that is hardly ever seen in any other diseased condition. It is important to note that acute or chronic nephritis, as a rule, is absent; parenchymatous and fatty changes predominate in the kidneys, which are large, soft and pale yellowish in color. The central nervous system commonly shows hemorrhagic infiltrations, usually microscopic, into the membranes as well as into the nerve substance. Inflammations are not unusual in eclampsia, particularly in the lungs, but these processes are now regarded as secondary and accidental rather than essential. The embolism of parenchymatous and other cells, especially placental, has attracted much notice.

This incomplete summary of the morphologic changes in eclampsia serves to outline the only basis as yet available for deductions as to the real nature of the pathogenesis of the disease.

Many of the older theories have been abandoned definitely, e. g., the infectious, because bacteriologic studies have not given uniform positive results, and the mechanical, which traced the eclampsia to ureteral obstruction, because the autopsies have failed to show any such obstruction. It is also clear that eclampsia can not be identified with uremia; for uremia may occur without the changes characteristic of eclampsia, and in eclampsia the renal changes are not constant and often not at all well marked. These theories all traced eclampsia to morbid conditions in the mother.

We have also a group of theories that conceive eclampsia as the outcome of an autointoxication dependent on pregnancy. Broadly speaking, this theory at present enjoys widest support, and it must be said that it is quite in harmony with the anatomic changes which are easily explainable as the result of the action of some toxic substance or substances of the nature perhaps of a cytolysin. The origin of the supposed toxic bodies has been referred to disturbances in the metabolism of the mother, and eclampsia regarded as analogous with other conditions peculiar to pregnancy, such as vomiting, chorea and certain psychic conditions. The various anatomic changes in pregnancy (pigmentary abnormalities, the formation of osteophytes, etc.) have been put in the same category so far as the cause is concerned. The poisonous substances have been supposed to be derivatives of protein decomposition, but as yet no one has succeeded in actually demonstrating the presence of any such substances in the blood or urine.

Other investigators trace the eclamptic intoxication to the fetus, and regard it as due to the absorption by the mother of fetal metabolic products. At present the fetal theory of eclampsia has many supporters, especially among clinicians. The theory is supported by the facts that eclampsia most frequently occurs in primiparæ and almost always toward the end of pregnancy, as well as by the favorable influence that birth exerts on the disease.

According to a third theory, the intoxication is placental in origin. This theory was advanced by Schmorl, who claimed that eclampsia is due to coagulative substances produced in the placenta. This theory receives some support from the presence of placental cells and chorionic villi in the blood of eclamptics (but these are present also to some extent in the blood in pregnancy uncomplicated by eclampsia), and by the multiple thromboses and embolism that constitute such a prominent feature in the pathologic anatomy of eclampsia. This theory is now being subjected to experimental testing, but as yet it is too early to formulate any definite conclusion as to its stability. It is interesting to note, however, that the placental theory of eclampsia seems to point the way to rational therapy.

THE MORBID ANATOMY OF ASTHENIC BULBAR PARALYSIS.

Under the designation of asthenic bulbar paralysis or myasthenia gravis pseudoparalytica has been described a condition characterized by weakness and undue readiness of fatigue in certain voluntary muscles, particularly those controlled by the bulbar nerves. The electric irritability of the affected muscles also is quickly exhausted. Sensibility, nutrition and reflex activity remain unaffected. In fatal cases, variable and inconstant changes have been found in the central and peripheral nervous systems and in the absence of definite knowledge the disorder has been considered of toxic origin. More recently, however, hyperplastic and neoplastic alterations have been described in the thymus gland in conjunction with deposits of lymphoid cells in the skeletal muscles.

At a recent meeting of the Pathological Society of London, Dr. E. Farquhar Buzzard[1] reported the results of postmortem examination in five cases of asthenic bulbar palsy, with a demonstration of specimens illustrative of the morbid anatomy. In three of the cases no marked changes were apparent to the naked eye. In one case the thymus gland was enlarged, weighing 41 grams and presenting microscopically the appearance of simple hypertrophy. In another case the anterior mediastinum was occupied by a large mass in the position of the thymus gland. The upper part of the mass resembled a new growth, while the lower part consisted of a multilocular cyst. Sections of the former exhibited strands of connective tissue, between which were large masses of round cells and few definite concentric corpuscles. The wall of the cystic portion contained besides occasional Hassall bodies. Nothing abnormal was discovered in the remains of the thymus gland from the other three cases. The central and peripheral nervous systems were carefully examined in all the cases, but no constant or important changes were detected. In all, however, small foci of cells resembling lymphocytes were found scattered irregularly between the cells of the viscera and in a number of muscles, with at times a small empty capillary vessel lined by a single layer of endothelium in close proximity. The appearances were suggestive of the escape of lymphocytes from the vessel and the term "lymphorrhage" is employed to describe the condition. In some instances gland cells adjacent to the cellular deposits had undergone degeneration or destruction. Some of the muscular fibers in the affected muscles were swollen and rounded, hyaline and granular in appearance and stained feebly.

Whether any significance is to be attached to the changes in the thymus gland at times observed in connection with asthenic bulbar paralysis can not as yet be determined. Comparable alterations have been found also in connection with another disorder of the muscles, namely, progressive muscular dystrophy. In cases in which they are not apparent, it is possible that functional disturbance may merely be unattended with structural alteration. Further, it may be that the changes described in the muscles may be secondary to the abnormalities on the part of the thymus gland. We have here at least a basis for more extended observation.

ARE FUSIFORM BACILLI AND THE ASSOCIATED SPIRILLA TRYPANOSOMES?

Considerable interest has arisen lately over the relation of various inflammatory and necrotic processes and fusiform bacilli, associated, as a rule, with long spirilla. Many articles have appeared on this subject in foreign literature, but it is only within the last three years that cases have been reported in America. The organisms have been found, usually together, in ulceromembranous angina (Vincent's) and stomatitis, pyorrhea alveolaris, noma, hospital gangrene, appendicitis, gangrenous ulcers of the penis, bronchiectasis, periostitis, abscess of the leg and cerebral abscess. Although it has not been absolutely proved that these organisms are the exciting agents in these pathologic lesions, it seems probable that they are. The bacilli have been isolated recently in pure culture. The spirilla have been cultivated, but only in mixed cultures. By further study of these organisms their relation to these various lesions may be settled.

Wright[1] has advanced the theory that these organisms are a stage in the life history of a tryanosome. He considers that the fusiform bacillus is not a bacillus, on account of its length. He points out that its vacuolation, its staining action with Leishman (blue with red chromatin bodies), its eel-like, undulatory movement, are highly suggestive of a protozoic origin, in spite of the absence of flagella and an undulatory membrane. He mentions that the placques found in the chronic conditions of the mouth, in which the bacilli are found, are suggestive of the placques which are a characteristic feature in dourine, a form of tryanosomic invasion in horses. He also considers the anemia of pyorrhea alveolaris indicative of a blood infection.

Mackie[2] has recently brought forth some evidence to prove this tryanosomic theory. He considers that the spirilla, fusiform bacilli, sickle-shaped bodies and ribbon-like bodies are all different stages of the same parasite. In carrying out some observations on changes undergone in tryanosomes under unfavorable conditions, he noticed the undulatory membrane and flagella disappear, the body of the animal becoming longer, thinner and more ribbon-shaped and the comma forms seeming to become quiescent. The protoplasm was seen to become granular. He says that the resemblance was very similar to forms seen in the pus of pyorrhea alveolaris.

This theory is of great interest, but further investigation along this line will be necessary before any conclusions can be drawn. It is probable that by continued study of cultures of the fusiform bacilli and spirilla, their bacillary or protozoic nature will be determined.

BRUTALITY OF FOOTBALL.

One of the most interesting news items of the past week was the announcement that President Roosevelt had succeeded in effecting an arrangement between the football captains and coaches of the more important eastern universities looking toward the elimination of brutality from the game. It is a rather striking coincidence that immediately after succeeding in bringing about peace between the combatants in the most serious and bloody war of modern times, our strenuous chief executive should next turn his attention to an attempt, at least, to do away with the brutality and fatalities which have marked the history of an American sport

THE NATURE OF PUERPERAL ECLAMPSIA.

Since Jürgens in 1884 described the peculiar changes in the liver in puerperal eclampsia, a large number of carefully studied cases has accumulated, so that it may be said that the pathologic anatomy of the disease now is fairly well understood. Perhaps the most active observer in this field has been Schmorl in Dresden, who has studied no less than 73 cases.

Harbitz, who recently reviewed all this work, points out that the most important, essential, anatomic changes in eclampsia concern the blood, in which there is more or less laking of the corpuscles and coagulation with the formation of thrombi and emboli; associated with and partly, at least, dependent on these alterations are hemorrhages, infarctions and necroses. The liver of eclampsia, with the congestion, infarctions and degenerations, presents a picture that is hardly ever seen in any other diseased condition. It is important to note that acute or chronic nephritis, as a rule, is absent; parenchymatous and fatty changes predominate in the kidneys, which are large, soft and pale yellowish in color. The central nervous system commonly shows hemorrhagic infiltrations, usually microscopic, into the membranes as well as into the nerve substance. Inflammations are not unusual in eclampsia, particularly in the lungs, but these processes are now regarded as secondary and accidental rather than essential. The embolism of parenchymatous and other cells, especially placental, has attracted much notice.

This incomplete summary of the morphologic changes in eclampsia serves to outline the only basis as yet available for deductions as to the real nature of the pathogenesis of the disease.

Many of the older theories have been abandoned definitely, e. g., the infectious, because bacteriologic studies have not given uniform positive results, and the mechanical, which traced the eclampsia to ureteral obstruction, because the autopsies have failed to show any such obstruction. It is also clear that eclampsia can not be identified with uremia; for uremia may occur without the changes characteristic of eclampsia, and in eclampsia the renal changes are not constant and often not at all well marked. These theories all traced eclampsia to morbid conditions in the mother.

We have also a group of theories that conceive eclampsia as the outcome of an autointoxication dependent on pregnancy. Broadly speaking, this theory at present enjoys widest support, and it must be said that it is quite in harmony with the anatomic changes which are easily explainable as the result of the action of some toxic substance or substances of the nature perhaps of a cytolysin. The origin of the supposed toxic bodies has been referred to disturbances in the metabolism of the mother, and eclampsia regarded as analogous with other conditions peculiar to pregnancy, such as vomiting, chorea and certain psychic conditions. The various anatomic changes in pregnancy (pigmentary abnormalities, the formation of osteophytes, etc.) have been put in the same category so far as the cause is concerned. The poisonous substances have been supposed to be derivatives of protein decomposition, but as yet no one has succeeded in actually demonstrating the presence of any such substances in the blood or urine.

Other investigators trace the eclamptic intoxication to the fetus, and regard it as due to the absorption by the mother of fetal metabolic products. At present the fetal theory of eclampsia has many supporters, especially among clinicians. The theory is supported by the facts that eclampsia most frequently occurs in primiparæ and almost always toward the end of pregnancy, as well as by the favorable influence that birth exerts on the disease.

According to a third theory, the intoxication is placental in origin. This theory was advanced by Schmorl, who claimed that eclampsia is due to coagulative substances produced in the placenta. This theory receives some support from the presence of placental cells and chorionic villi in the blood of eclamptics (but these are present also to some extent in the blood in pregnancy uncomplicated by eclampsia), and by the multiple thromboses and embolism that constitute such a prominent feature in the pathologic anatomy of eclampsia. This theory is now being subjected to experimental testing, but as yet it is too early to formulate any definite conclusion as to its stability. It is interesting to note, however, that the placental theory of eclampsia seems to point the way to rational therapy.

THE MORBID ANATOMY OF ASTHENIC BULBAR PARALYSIS.

Under the designation of asthenic bulbar paralysis or myasthenia gravis pseudoparalytica has been described a condition characterized by weakness and undue readiness of fatigue in certain voluntary muscles, particularly those controlled by the bulbar nerves. The electric irritability of the affected muscles also is quickly exhausted. Sensibility, nutrition and reflex activity remain unaffected. In fatal cases, variable and inconstant changes have been found in the central and peripheral nervous systems and in the absence of definite knowledge the disorder has been considered of toxic origin. More recently, however, hyperplastic and neoplastic alterations have been described in the thymus gland in conjunction with deposits of lymphoid cells in the skeletal muscles.

At a recent meeting of the Pathological Society of London, Dr. E. Farquhar Buzzard[1] reported the results of postmortem examination in five cases of asthenic bulbar palsy, with a demonstration of specimens illustrative of the morbid anatomy. In three of the cases no marked changes were apparent to the naked eye. In one case the thymus gland was enlarged, weighing 41 grams and presenting microscopically the appearance of simple hypertrophy. In another case the anterior mediastinum was occupied by a large mass in the position of the thymus gland. The upper part of the mass resembled a new growth, while the lower part consisted of a multilocular cyst. Sections of the former exhibited strands of connective tissue, between which were large masses of round cells and few definite concentric corpuscles. The wall of the cystic portion contained besides occasional Hassall bodies. Nothing abnormal was discovered in the remains of the thymus gland from the other three cases. The central and peripheral nervous systems were carefully examined in all the cases, but no constant or important changes were detected. In all, however, small foci of cells resembling lymphocytes were found scattered irregularly between the cells of the viscera and in a number of muscles, with at times a small empty capillary vessel lined by a single layer of endothelium in close proximity. The appearances were suggestive of the escape of lymphocytes from the vessel and the term "lymphorrhage" is employed to describe the condition. In some instances gland cells adjacent to the cellular deposits had undergone degeneration or destruction. Some of the muscular fibers in the affected muscles were swollen and rounded, hyaline and granular in appearance and stained feebly.

Whether any significance is to be attached to the changes in the thymus gland at times observed in connection with asthenic bulbar paralysis can not as yet be determined. Comparable alterations have been found also in connection with another disorder of the muscles, namely, progressive muscular dystrophy. In cases in which they are not apparent, it is possible that functional disturbance may merely be unattended with structural alteration. Further, it may be that the changes described in the muscles may be secondary to the abnormalities on the part of the thymus gland. We have here at least a basis for more extended observation.

ARE FUSIFORM BACILLI AND THE ASSOCIATED SPIRILLA TRYPANOSOMES?

Considerable interest has arisen lately over the relation of various inflammatory and necrotic processes and fusiform bacilli, associated, as a rule, with long spirilla. Many articles have appeared on this subject in foreign literature, but it is only within the last three years that cases have been reported in America. The organisms have been found, usually together, in ulceromembranous angina (Vincent's) and stomatitis, pyorrhea alveolaris, noma, hospital gangrene, appendicitis, gangrenous ulcers of the penis, bronchiectasis, periostitis, abscess of the leg and cerebral abscess. Although it has not been absolutely proved that these organisms are the exciting agents in these pathologic lesions, it seems probable that they are. The bacilli have been isolated recently in pure culture. The spirilla have been cultivated, but only in mixed cultures. By further study of these organisms their relation to these various lesions may be settled.

Wright[1] has advanced the theory that these organisms are a stage in the life history of a tryanosome. He considers that the fusiform bacillus is not a bacillus, on account of its length. He points out that its vacuolation, its staining action with Leishman (blue with red chromatin bodies), its eel-like, undulatory movement, are highly suggestive of a protozoic origin, in spite of the absence of flagella and an undulatory membrane. He mentions that the placques found in the chronic conditions of the mouth, in which the bacilli are found, are suggestive of the placques which are a characteristic feature in dourine, a form of tryanosomic invasion in horses. He also considers the anemia of pyorrhea alveolaris indicative of a blood infection.

Mackie[2] has recently brought forth some evidence to prove this tryanosomic theory. He considers that the spirilla, fusiform bacilli, sickle-shaped bodies and ribbon-like bodies are all different stages of the same parasite. In carrying out some observations on changes undergone in tryanosomes under unfavorable conditions, he noticed the undulatory membrane and flagella disappear, the body of the animal becoming longer, thinner and more ribbon-shaped and the comma forms seeming to become quiescent. The protoplasm was seen to become granular. He says that the resemblance was very similar to forms seen in the pus of pyorrhea alveolaris.

This theory is of great interest, but further investigation along this line will be necessary before any conclusions can be drawn. It is probable that by continued study of cultures of the fusiform bacilli and spirilla, their bacillary or protozoic nature will be determined.

BRUTALITY OF FOOTBALL.

One of the most interesting news items of the past week was the announcement that President Roosevelt had succeeded in effecting an arrangement between the football captains and coaches of the more important eastern universities looking toward the elimination of brutality from the game. It is a rather striking coincidence that immediately after succeeding in bringing about peace between the combatants in the most serious and bloody war of modern times, our strenuous chief executive should next turn his attention to an attempt, at least, to do away with the brutality and fatalities which have marked the history of an American sport for the last twenty years. We say an attempt advisedly, because the president of one of the most important universities in the East said in an apparently hopeless sort of way, when he heard of President Roosevelt's intervention, that he wished him success. He confessed to having tried himself and failed. It will indeed be a reflection on our American civilization if, after conciliating Russia and Japan, President Roosevelt fails to prevent further "killings" in football.

[1] Lancet, May 27, 1905, p. 1421.

[1] Lancet, July 9, 1904, p. 73.

[2] Lancet, July 8, 1905, p. 110.

It is not much extenuation of the record of fatalities and of injuries that are more than death to say that they have occurred as a rule in minor college teams and not among the hardened athletes of the great universities. It is the great universities of the land that are expected to set an example in every way to the minor educational institutions of the country. In their hands has been the modification of the rules in such ways as to eliminate all possibility of brutality taking the place of sport. It is idle to say that it is impossible to do away with brutality.

The recent authoritative announcement that any Army or Naval cadet who, during the games played by the respective academies, may be declared by the umpire to have been deliberately brutal, will be dismissed from the service, represents the right way to treat this subject. Of course, any player who does a brutal act to win a game, no matter how great the provocation, is guilty of conduct unbecoming an officer and a gentleman. To cashier him from the service of the United States is the only right thing to do. This same regulation should be in effect at the great universities. Any football player who is deliberately brutal, that is, who performs an act which is meant to injure a player on the other side in order to put him out of the game and so weaken his side, should be disbarred from playing, not alone from that game, but from any other game. Although it is hopeless to look for any change in the rules during the present year, now is the time to make changes for next season. The play can be made more open by modifications in the rules, and that this has not been done is due to the fact that the committee has apparently been afraid of making the game uninteresting by radical changes.

We wish President Roosevelt as distinguished success in this last life-saving attempt as in his previous brilliant achievement, and we can assure him that the medical profession of the country will be with him in the enterprise.

THE PUBLICITY OF HEALTH RECORDS.

There is much that might be said that is good of American progress in hygienic matters, but the criticisms in Dr. Fulton's address, published in this issue, are certainly called for. We in this country have never been strong in the matter of vital statistics; over a large portion of our territory the attempts at their collection are almost farcical and, even where they are at their best, there is, as he points out, much room for reform. It is the second point of his criticism, however, that most calls for our attention here. The disreputable, and, we might say, criminal use of the health records for commercial purposes, as he shows, is appalling, and strongly suggests that even worse remains behind. The possibilities of blackmailing from a free access of everyone to these records are very apparent. Moreover, as the tendency to increase the number of notifiable diseases extends, and there is good reason for its doing so, the evil possibilities are greatly enhanced. There may be some excuse for allowing insurance companies access to such data, though we do not see that they have any special rights in the matter, but why nostrum venders, quacks, and the like, should be allowed to utilize them is beyond reasonable comprehension. Moreover, if these things are to be so, and the condition is generally understood, notification laws must necessarily fail. There is a striking inconsistency in a state whose legislation puts rigid restrictions around matters of medical secrecy and privilege and yet allows its mortality and health records to be at the command of everyone, or at least any one who can obtain the political favor of the privilege of their consultation. Of course, such records should be available to the proper parties, but this should be under such restrictions as would prevent any violation of their strictly confidential character. At present it appears, from Fulton's researches on the matter, that they are utilized largely for the profit of gross commercialism and political grafters. There is a good opportunity here for a strike for reform.

DEPORTING NON-RESIDENT DEPENDENTS.

A considerable movement of dependent insane may be looked for in various states owing to the more or less far-reaching results of the operation of a new law in New York. The latter state is investigating the records and is sending away insane persons whose legal residence is in other states, which, therefore, should bear the expense of their care. Something of a sensation was caused in one state on the receipt of several such patients, and it has caused the authorities of that state to prepare to make a similar examination of records and a clearing of their own asylums. In certain states the dependent insane for whose care those states are not legally liable require the expenditure of thousands of dollars, and taxpayers have a right to object. We trust that the investigations will be conducted with great care and all unnecessary excitement of patients avoided. Sympathetic, tactful dealings will prevent the harm that might easily be done.

MONEY AND MICROBES.

It is said that the public has been so far educated as to the dangers of microbic infection that the redemption bureau of the Treasury Department is overworked by the turning in of dirty currency and the demand for fresh bills. Perhaps the campaign for the Post check currency, which has disseminated so many warnings about dirty money, is in part responsible for this interest on the part of the public. We welcome it as we shall welcome the check currency—when the express companies' lobby is overthrown.

MEDICAL PESSIMISM.

While man is mortal the practice of medicine will always be in one sense of the word a losing game. That fact, however, does not justify a pessimistic estimate of its usefulness and of its progress such as have recently been made by one or two more or less prominent foreign writers on the subject. The public generally has a sort of notion that diseases are treated by specific remedies and this is the basis of their faith in the prevalent quackery of all times. The fact that we do not have specifics for every disease is no justification for the statement that we can not intervene successfully in any disease, nor for the recent utterance of an English physician that we "can practically do nothing to prevent death from a virulent bacterial invasion or to bring about a cure." Every successful practitioner can honestly contradict this from his own experience. While the thoughtful and conscientious educated physician has no delusions as to his limitations, he does not, on the other hand, have any reason to feel that he is a humbug profiting by the delusions of others. The usefulness of the physician consists not merely in warding off death when actual severe illness has occurred—and this he can do in many cases—but also in shortening the non-fatal ailments and in mitigating the chronic and hopeless ones. If we consider preventive medicine alone the case is still better. There is hardly an epidemic disease dreaded in the past that has a tithe of its old terrors to the educated physician or sanitarian of to-day. The problems of disease are being more successfully studied at the present time than at any period in the past, not only by the laboratory and hospital workers, but more than ever before by those engaged in general and special practice. That much of this work is not directly fruitful need not be denied, but it is only by working over the great mass of ore that the real gold is extracted, and there has been no work so beneficial and promising, taking it as a whole, as that which has been done in the last twenty years and is still being continued. It is well to know our deficiencies, and confession is said to be good for the soul, but pessimism in medicine, like pessimism elsewhere, is morbid and not conducive to the good of the individual, the physician or the world.

BIRTH INSURANCE.

In a number of European countries maternity insurance is a long-established fact. Italy has recently provided for government birth insurance. The recent unfavorable opinion of the Minnesota insurance commissioner is therefore of present interest. He ruled that "maternity does not present the characteristics of a thing which may properly be insured against," and refused the American Mothers' Birth Insurance Association permission to do business in the state. The *Chronicle* (insurance paper) thinks that this decision is not well founded in reason. Of course, there is no financial loss in maternity, but there is necessary and immediate expense to be met, and this is a proper subject for insurance. Maternity in a sense is voluntary, but only in part, and so, to at least an equal degree, are death, sickness, casualty and fire, all of which are recognized as insurable events.

CENTENNIAL CELEBRATION OF A UNITED PROFESSION IN NEW YORK.

As will be noted in our News department, the New York State Medical Association, at its annual meeting this week, again endorsed the report of the committee on amalgamation with the Medical Society of the State of New York. As will be remembered, a year ago the report of the committee was adopted but it was afterward discovered that certain legal formalities had to be gone through with before the New York State Medical Association could give up its existence and merge into the society. The legal difficulties involved notifying every member of the association and giving him the right to vote on the proposition. The result, judging from a telegram received as we go to press, shows that the vote in favor of amalgamation was almost unanimous. The other legal formalities, as we understand it, will necessitate but little time, and it is now hoped that the next annual meeting of the Medical Society of the State of New York, to be held in Albany next January—which will be its hundredth meeting—will be a grand centennial celebration of a united profession of the Empire State. The congratulations of the physicians of the entire country are extended, we are sure, to the members of the association and of the society who have worked so diligently to bring about this union.

Medical News

ALABAMA.

Physician Fined.—Dr. M. D. Welborn, Ezell Station, near Pratt City, who was arrested several days ago on the charge of selling cocain, was fined $100 and costs October 3.

Medical Colleges Opened.—The Birmingham Medical College opened for its annual session October 3. Addresses were made by Drs. Russell M. W. Cunningham, Ensley; Dr. Edward H. Sholl, Dr. John C. Le Grande and others.——The medical department of the University of Alabama, Mobile, opened October 5.

Personal.—Dr. William T. Berry has been elected professor of orthopedic surgery in the Birmingham Medical College, a chair established this year.——Dr. Shirley Bragg, Montgomery, has been made president of the board of convict inspectors, and Dr. Nathaniel G. Clark, Ensley, physician inspector of convicts of the state.

Alumni Organized.—The Alumni Association of Birmingham Medical College met for organization October 3 and elected the following officers: President, Dr. Joseph H. Edwards, Wylam; vice-presidents, Drs. Ira C. Skinner, Selma, and Zachary B. Chamblee, North Birmingham, and secretary and treasurer, Dr. J. F. Hogan, Birmingham.

Winter Hospital Staff.—The official staff of the City Hospital of Mobile for the winter months announces as follows: Medicine—Drs. Henry A. Moody and Charles A. Mohr; surgery—Drs. Rhett Goode, William R. Jackson, Paul J. M. Acker and Perry J. Howard; obstetrics—Dr. Tucker H. Frazier; ophthalmology and laryngology—Drs. William H. Sanders and Ruffin A. Wright; neurology—Dr. Eugene D. Bondurant; gynecology—Dr. J. Buckner Killebrew, and resident physician, Dr. Ernest S. Feagin.

CALIFORNIA.

Denied Use of Mails.—The Vacuum Medicine Company, San Francisco, has been denied the use of the mails by the post-office department.

Sanatorium to Be Enlarged.—A new building is to be erected for the Agnew Sanatorium, San Diego, four stories in height, to accommodate about 80 patients.

Clinic Opened.—A free medical and surgical clinic was opened at the Sisters' Hospital, Los Angeles, October 2, with Drs. Edward T. Dillon, Ernest A. Bryant and Joseph M. King in charge.

College Opens.—The opening exercises of the Medical College of the University of Southern California, Los Angeles, were held October 5. Dr. Lyman B. Stookey has been added to the faculty as professor of physiology and physiologic chemistry.

Personal.—Dr. H. Miller Robertson, Arlington, has returned from Europe.——Dr. James H. Glass has returned to his home in Paso Robles after an absence of about two years.——Dr. Walter S. Thorne and family, San Francisco, have returned from Europe.

Medical Library Site Donated.—Dr. Walter Jarvis Barlow has donated the site for a medical library building to be erected opposite the Medical College of the University of Southern California, Los Angeles. The estimated cost of the building is $25,000.

Hospital Cornerstone Laid.—The cornerstone of the new German Hospital, San Francisco, was laid October 8 with elaborate ceremony. The new hospital, which adjoins the present structure, will be of steel, fireproof construction and will cost about $400,000.

New Hospital Required.—The Sequoia Hospital, Eureka, erected only about two years ago, has been found to be inadequate to the needs of the locality. A site has been purchased for $15,000, on which a hospital to cost from $60,000 to $75,000 will be erected.

Farmers Victimized.—A number of farmers living in the vicinity of Merced were recently made the victims of two men traveling under the guise of doctors, who offered to make examinations free of charge, and on doing so were appalled to find the patients in serious condition and requiring immediate care for which an advance fee was required. After receiving the fee the "doctors" did not return.

COLORADO.

Personal.—Dr. Fleming H. King, Boulder, was severely burned in an attempt to extinguish a fire in his office October 6.

Health of Colorado Springs.—During August 29 deaths were reported, equivalent to an annual death rate of 11.60 per 1,000. Of the 29 deaths 15 were due to tuberculosis.

Colorado State Medical Society.—The thirty-fifth annual meeting of this society was held in Colorado Springs, October 3-5. Dr. Frank Finney, La Junta, presided. The entertainments provided for the visiting members included a banquet October 3 for the members, a theater party for their ladies; on October 4 a smoker and vaudeville for both ladies and gentlemen, and a tea on the same evening for the ladies, given by Dr. Josephine L. Peavey. The papers presented were of unusually high grade. In the president's address he recommended the organization of a state propaganda for the consideration of tuberculosis that the people might be educated and the spread of the disease thereby prevented. The following officers were elected: President, Dr. Horace G. Wetherill, Denver; vice-presidents, Drs. E. T. Boyd, Leadville; Perry Jaffa, Trinidad, and Charles A. Ringle, Greeley; secretary, Dr. Melville Black, Denver (re-elected); treasurer, Dr. S. Edwin Solly, Colorado Springs; publication committee, Drs. Edward Jackson, J. M. Blaine and Josiah N. Hall, Denver; councilors, Drs. E. T. Boyd, Leadville, and Frank Finney, La Junta; delegate to American Medical Association, Dr. Hubert Work, Pueblo, and alternate, Dr. Heman R. Bull, Grand Junction. The session of 1906 will be held in Denver.

DELAWARE.

Donation Day.—October 5 was donation day for the Delaware Hospital, Wilmington, when donations of all kinds were received and the institution was kept open all day for inspection.

State Hospital Overcrowded.—At the meeting of the trustees of the Delaware State Hospital, Farnhurst, the report of the superintendent showed that there were 379 inmates, the largest number in the history of the institution. He stated that the institution was overcrowded and asked that the legislature be petitioned to enlarge the building.

Examiners Nominated.—The Delaware State Medical Society, at its annual meeting, presented the following names to the governor, from which two members of the state board of examiners are to be selected: Drs. George W. Marshall, Milford; Ezekiel W. Cooper, Camden; Francis L. Springer, Newport; L. August H. Bishop, Dover; Robert B. Hopkins, Milton; L. C. Carrow and Jacob C. Knowles, Seaford, and James A. Draper, Ralph P. Stubbs and Henry W. Briggs, Wilmington.

State Society Meeting.—The Delaware State Medical Society held its one hundred and sixteenth annual meeting at the Delaware Hospital, Wilmington, October 10, the president, Dr. Alexander I. Lowber, in the chair. The address of welcome was made by William S. Ellis and the response by Dr. Willard Springer, Wilmington. In his annual address the president dwelt on the ravages of tuberculosis and the necessity of the establishment of a state sanatorium. The House of Delegates met for the first time in the history of the society. It is composed of ten members, six from New Castle County, two from Kent County and two from Sussex County. The following officers were elected: President, Dr. John Palmer, Jr., Wilmington; vice-presidents, Drs. G. Frank Jones, Georgetown, and Frank Verdin, Kenton; secretary, Dr. George W. K. Forrest, Wilmington; treasurer, Dr. William C. Pierce, Wilmington; delegate to the American Medical Association, Dr. Hiram R. Burton, Lewes, and Dr. Frank Belville, Delaware City, alternate; and councilors, Drs. Peter W. Tomlinson, Wilmington; James H. Wilson, Dover, and James Bryshaw, Sussex.

DISTRICT OF COLUMBIA.

Physician Fined.—Anthony Mandis, who advertised that he had medicine for the cure of epilepsy and was charged with being an unlicensed physician, was fined $50 in the Washington police court September 29.

Georgetown University Hospital.—The reports from the committee in charge of the lawn fête for the benefit of the Georgetown University Hospital show that about $1,500 will be realized. The hospital is in a flourishing condition and is doing excellent work.

Medical and Surgical Society.—The Medical and Surgical Society of the District of Columbia held its eighteenth annual meeting October 6 at the residence of the president, Dr. Presley C. Hunt, who in his address, reviewed the work of the society for the year just closed. Dr. Oscar A. M. McKimmie was elected president.

Health of the District.—The report of the health officer for the week ended October 7 shows the total number of deaths to have been 114, of which number 66 were white and 48 colorded; number of births, 133 (white 100, colored 33), and stillbirths 11 (white 7, colored 4). At the close of the week there were under treatment 32 cases of diphtheria, 9 of scarlet fever, 240 of typhoid fever, and 1 of smallpox.

IDAHO.

State Officers Elected.—At the annual meeting of the Idaho State Medical Society, held in Boise, October 6 and 7, Dr. John B. Morris, Lewiston, was elected president; Dr. Erwin W. Kleinman, Shoshone, vice-president, and Dr. Ed. E. Maxey, Boise, secretary and treasurer (re-elected). The society will meet at Lewiston next year.

ILLINOIS.

Physician Robbed.—Dr. Samuel S. Salisbury, Tolono, was robbed of a watch by two holdup men October 1. Fortunately, the robbers failed to find his purse.

"Cross-eye" Doctor Levants.—"Dr." C. A. Lambert, who has advertised wonderful cures for cross-eyes, etc., in Coal City, is said to have left Morris suddenly, leaving unpaid accounts behind him.

The Oak Park Hospital Trouble.—The latest developments in the Oak Park Hospital Association proceedings are the withdrawal by Dr. J. W. Tope of his offer to purchase the assets of the association, the defeat of a resolution to abandon the association, and the unanimous adoption of a substitute amendment to consider the question on "hospital or no hospital." The association, therefore, is again facing the financial difficulties which have so long beset it.

Personal.—Dr. and Mrs. Charles W. Hall, Kewanee, have returned from a visit to [illegible] Dr. Peter J. Reynolds, Dwight, was thrown from [illegible] 28, breaking his leg.——Dr. Josiah T. Kretsinger, Leaf River, has returned from a trip to the Pacific Coast.——Dr. Alpheus A. Bondurant, Cairo, who has been seriously ill, is reported to be convalescent.——Dr. Joseph Sheurich, Philo, was taken to the Burnham Hospital, Champaign, October 3, suffering from a bullet wound.——Dr. Albert C. Johnson, Sidell, is seriously ill at the home of his parents, near Horace.

Chicago.

Personal.—Dr. Plumer M. Woodworth has been appointed a trustee of the Illinois Northern Hospital for the Insane, Elgin.

Medical Student Dies.—Wesley C. Lowther, a student at the Northwestern University Medical College from West Virginia, was found dead in his bed October 8 from asphyxiation. The death is believed to be accidental.

Increases Appropriation.—The finance committee of the City Council has voted an additional appropriation of $8,550 for the Health Department, which, as the lay press announces, "will be used for the following employes: One stenographer, six plumbing inspectors, two clerks, six meat and food inspectors, four horses and one buggy."

The City's Deaths.—For the week ended October 14 the mortality of the city was 477, 5 more than for the previous week and 53 more than for the corresponding week of 1904. This is equivalent to an annual death rate of 12.4. The principal causes of death were: Acute intestinal diseases, 69; consumption, 53; violence and suicide, 47; heart diseases and pneumonia, each 38; Bright's disease, 28; cancer, 24, and nervous diseases, 21.

College Becomes Integral Part of University.—The Northwestern University Medical School (Chicago Medical College), which previously has held only an affiliated connection with the Northwestern University, became an integral part of that institution by a vote of the board of trustees at its quarterly meeting, held October 10. The medical school turns over property to the university valued at $353,000, which includes the college building at Dearborn and Twenty-fourth Streets.

New Policlinic Hospital.—The Chicago Policlinic has given to the Northern Trust Company a trust deed to its property to secure a bond issue of $300,000 maturing in 1935 and bearing interest at 4 per cent. The property in the deed includes the new site of the hospital at Oak Street and La Salle Avenue and the present hospital on Chicago Avenue. The new hospital will be six stories in height with a frontage of 200 feet, of fireproof, steel construction, and will accommodate 150 patients.

INDIANA.

Disease Closes Schools.—The public schools of Petersburg were closed October 2 because of an epidemic of diphtheria.—— The schools of Alvord have also been closed for the same reason.

Accident and Illness.—Dr. Calvin Carter, Brookville, was struck in the face by the head of a sledge-hammer October 5, breaking his nose and causing other injuries.——Dr. William Dederick, Warsaw, is seriously ill.

College Transformed into Hospital.—The Fort Wayne district of the Northern Indiana Methodist Conference has decided to purchase the Fort Wayne Medical College building and convert it into a deaconess' hospital.

Found Guilty a Second Time.—William Kluge, Indianapolis, who was fined $50 a few months ago for practicing medicine without a license, was found guilty October 2 of a similar offense and was fined $25 and costs.

Convicted of Fraud.—Dr. Charles Morehouse, who was convicted of conspiring to defraud Mrs. Martha McDonald of South Bend, was found guilty of conspiracy in committing a felony and sentenced to the Michigan City penitentiary for an indeterminate period of not less than two nor more than fourteen years, and to pay a fine of $25.

Continued Merger.—On October 9 the Fort Wayne Medical College was merged into and became a part of the medical department of Purdue University. Under the new arrangement five members of the faculty will be continued in the faculty of the medical department, and Dr. Christian B. Stemen has been made vice-dean of the faculty.

Personal.—Dr. John N. Hurty, Indianapolis, secretary of the State Board of Health, who has been seriously ill with inflammatory rheumatism, has gone to Atlantic City in the hope of regaining his health.——Dr. John S. Reagan has been appointed physician to the Indiana Boys' School, Plainfield, vice Dr. Amos Carter.——Dr. Edwin M. Trook, Marion, has been appointed surgeon for the Kokomo, Marion & Western traction line.

KANSAS.

South Kansas Medical Society.—This society held its annual meeting at Wichita October 19-20.

Diphtheria Closes Schools.—The State Normal School and public schools of Hays City have been closed on account of the prevalence of diphtheria.

New Hospital.—The new hospital recently erected at Larned by Drs. Charles H. Ewing, William C. MacCurdy and Arthur W. H. Seiple, was opened to the public October 9.

For Sanitary Railway Cars.—The State Board of Health has authorized its secretary, Dr. S. Jay Crumbine, to co-operate with other states west of the Mississippi River in securing uniform legislation for railroad car sanitation.

Hospital Directors Appointed.—Drs. Josephus P. Stewart, Benjamin F. Morgan, and Messrs. C. C. Stillman, Olsen and Alquist, have been appointed directors of the Clay Center Hospital, and the first-named was elected president of the board.

Personal.—Dr Samuel W. Spitler, Wellington, has returned from New York.——Dr. W. R. Palmer, Kansas City, has been appointed assistant in the clinical department of the German Hospital.——Dr. Homer F. Parr, Wellington, has located in Carlsbad, N. M.

August Diseases.—During the month of August 87 cases of tuberculosis and 44 deaths were reported in Kansas; 264 cases of typhoid fever, with 33 deaths; 65 cases of diphtheria, with 9 deaths; 61 cases of scarlet fever, with 1 death; 12 cases of measles, with 1 death; and 99 cases of smallpox, with 1 death.

A Good Meeting.—The meeting of Sumner County Medical Society, Wellington, September 15, was of exceptional interest, 24 of the 32 members being present. Dr Samuel W. Spitler, Wellington, presented a report of the American Medical Association meeting. Dr. Oliver J. Furst, Peabody, councilor of the district, was present, and Dr. Hoxie outlined the aims of the Kansas University for higher medical education.

KENTUCKY.

Diphtheria Closes Schools.—The public schools of Eminence, LaFayette and Hickman have been closed on account of the prevalence of diphtheria.

Appeal for Hospital.—The trustees of the Good Samaritan Hospital, Lexington, have issued an appeal for $50,000 to erect a new building for the hospital, which is urgently required.

Will Serve Without Pay.—The names of twelve Frankfort physicians have been presented to the prison commissioners, each of whom agrees to serve as prison physician for a month without pay, or until the expiration of the term of office of the late Dr. Hugh L. Tobin, provided the salary is given to the widow of the deceased physician.

State Medical Examiner Appointed.—Prof. W. P. St. Clair, head of the department of Latin in the Male High School, Louisville, has been appointed state medical examiner by the State Board of Health under the law passed in 1904, requiring that those who entered the medical schools of Kentucky shall be required to have a preliminary education corresponding to that furnished by a first-class high school.

Speers Hospital Report.—The annual report of the Speers Memorial Hospital, Dayton, shows that during the fiscal year just ended 489 patients were cared for and 165 surgical operations were performed; 10 deaths occurred, but 6 of the patients were moribund when operated on. The following staff has been appointed: Gynecology, Dr. Magnus A. Tate, Covington; surgery, Dr. John L. Pythian, Newport; medicine, Dr. J. W. Youtsey, Newport; neurology, Dr. Willis W. Ranshaw, Covington; dermatology, Dr. William E. Truesdell, Newport; pediatrics, Dr. Joseph J. Bock, Newport; obstetrics, Dr. William W. Tarvin, Covington; and pathology, Dr. Claude Youtsey, Newport.

Personal.—Dr. Charles B. Schoolfield, Dayton, is critically ill.——Dr. John D. Hamilton, Louisville, who has been seriously ill for a long time, is reported improving.——Dr. Joseph B. Marvin and family, Louisville, sailed from London on the *Minnehaha* for New York, September 23.——Dr. Clyde Vermillion and family, Russell, have moved to Idaho on account of the illness of the former.——The Kentucky School of Medicine has elected Dr. Granville S. Hanes clinical professor of rectal diseases.——Dr. Emilius M. McKee, Lexington, has been chosen superintendent of St. Vincent Hospital, St. Louis. ——Dr. Edward L. David, Louisville, who is about to move to Philadelphia, was the guest of honor at a banquet given by the subfaculty of the University of Louisville, October 2.

LOUISIANA.

Personal.—Dr. Felix A. La Rue, New Orleans, visited Emmittsburg, Md., October 6 to celebrate the silver jubilee of his graduation at Mt. St. Mary's College, in that town, in 1880.

School of Tropical Medicine Proposed.—The president of Tulane University announces the proposal to found a school of tropical medicine in connection with that institution. This, he thinks, would attract students not only from the South, but from Cuba, Mexico and Central America.

Physician and Town Marshal Fight.—In a desperate encounter between Dr. David B. Garland and town marshal W. J. Thaxton, Bernice, on October 3, the latter sustained two bullet wounds and six or eight knife wounds. Dr. Garland was stabbed near the heart and both are expected to die.

MARYLAND.

Personal.—Dr. T. Rowe Price, Glyndon, Baltimore County, has gone to the Pacific coast.——Dr. T. Chalmers Peebles, Lutherville, has moved to Falmouth, Mass.

Typhoid at Hagerstown.—About 45 cases of typhoid fever have been reported in Hagerstown since June 1. Examination of the drinking water by the State Board of Health is said to have been negative.

Baltimore.

To Buy Portrait.—A fund is being raised at the college hospital to procure a portrait of Prof. Thomas S. Latimer to be hung in the college library.

Student Dies.—Herbert E. Taber, a third-year student in the College of Physicians and Surgeons, Baltimore, died from typhoid fever, October 10, in Providence, R. I.

Personal.—Dr. Archibald W. Graham has been appointed assistant resident physician at Bayview Hospital, vice Dr. W. W. Riha, appointed assistant physician to Danvers (Mass.) Hospital for the Insane.

Staff Changes.—Dr. G. R. Holden has resigned as resident gynecologist, and Dr. A. M. Little as resident obstetrician at the Johns Hopkins Hospital. Their places have been supplied by Drs. Stephen Rushmore and F. C. Goldsborough, respectively. Dr. Holden will go to Jacksonville, Fla., to practice, and Dr. Little will become superintendent of the maternity connected with McGill University, Montreal, Canada.

MASSACHUSETTS.

Physician Fined.—Dr. Louis H. Clark, Holyoke, was fined $15, September 18, on the charge of violating the speed laws of the town of Leicester.

Hospital Field Day.—As the result of the hospital field day for the Milford Hospital, $943.50 was realized and turned over to the treasurer of the institution.

New Hospital for Cambridge.—The new Emergency Hospital situated in the heart of the factory district in Cambridge, was opened October 1. Dr. George V. Buehler is in charge.

Acquitted.—Dr. Victor Bychower, Boston, charged with performing an illegal operation on Minnie Cohen, was discharged from custody, August 30, as the prosecution failed to sustain its case.

Offers to Give Laboratory.—Andrew Carnegie has offered to give Smith College, Northampton, one-half of $125,000 required for a biologic laboratory on condition that friends of the college secure the remainder of the amount.

Pleads Guilty.—At the session of the District Court, August 7, at Ware, Dr. J. A. Dorval pleaded guilty to the charge of practicing medicine without a license, and was held to the criminal session of the Superior Court, December 18.

Physicians Lose Suit.—Drs. John M. French, Milford, and Arthur M. Rounds, Norton, who sued the United Order of the Golden Star for $1,500, alleged to be due them for services as grand medical examiners, were non-suited October 4.

Operating Building Presented.—It is understood that A. C. Houghton will present to the North Adams Hospital an operating building separate from the other hospital structures and equipped in accordance with the demands of modern surgery.

Sent to Prison.—Dr. Charles R. Greeley, South Weymouth, charged with a statutory offense, was sentenced to the House of Correction for one year at Dedham, September 23.——Dr. Ovid M. Paulhaus, Haverhill, charged with committing an illegal operation which caused the death of Mrs. Arthur Goodman, pleaded guilty, and was sentenced to imprisonment for not less than six nor more than six and one-half years in the state prison, September 18.

Dispensary Report.—The one hundred and ninth annual meeting of the Boston Dispensary, held October 13, showed a record of its largest year; 101,280 patients were treated at the central and Roxbury offices; 21,858 visits were made at homes by 14 district physicians, each accompanied by a nurse from the Instructive District Nursing Association; 92,063 prescriptions were filled on orders from the medical staff. There are now 18 departments at the central office, and there is great need of more room. For this addition $100,000 is needed, of which $20,874 has been subscribed. The regular work of the institution is maintained by its income, but there is nothing available for enlargement.

Personal.—Dr. Charles Harrington, secretary of the State Board of Health, has sailed for Europe. He will present at the International Dairy Conference in Paris, October 16-19, the work which has been done by the board along those lines.——Dr. Charles H. Turner, Holyoke, has returned from England and will locate in Haverhill.——Dr. Louis L. Auger, Worcester, has returned from Europe.——Dr. John O'Shea has been appointed house surgeon at the Boston City Hospital.——Dr. John H. Lindsey, Fall River, has resigned as a member of the staff of the city hospital.——Dr. Edward H. Trowbridge, Worcester, has returned from a trip abroad.——Dr. Frank W. White, Boston, returned from Europe October 2.

Charities Get Quarter of a Million.—By the will of Charles Tidd Baker, late a prominent insurance broker of Boston, $250,000 is devised to charities. Those largely medical are: Convalescents' Home for Children's Hospital, $15,000; Boston Home for Incurables, $10,000; Children's Hospital, Boston, $10,000; Boston Floating Hospital, $10,000; Hospital Cottages for Children, Baldwinsville, $5,000; Boston Lying-in Hospital, $5,000; Free Home for Consumptives, Dorchester, $5,000; St. Luke's Convalescent Home, $5,000; Massachusetts Infant Asylum, $5,000; Willard Hospital, Bedford, $5,000. All of these bequests are to be paid, however, only after the death of the testator's sister, who is to have the income of his estate during her lifetime.

County Society Active.—The Essex South District Medical Society celebrates its centennial year this year, as it was organized in Salem Nov. 4, 1805. The program for the centennial year is unusually interesting, and includes an illustrated lecture by Dr. George M. Gould, Philadelphia, on "The Struggle for Fresh Air and Light"; a centennial celebration at which Dr. Holyoke of Holyoke will read a paper on the life of his ancestor, Dr. Edward A. Holyoke, who was the founder and first president of the society, and also first president of the Massachusetts Medical Society. The president of the Massachusetts Medical Society will respond for the parent organization, and historical papers, each covering a period of a quarter of a century, will be presented by members of the society. Among other topics to be presented during the year are: "Tuberculosis; Its Treatment and Prevention," "Pure Foods" and "Facts and Fallacies Concerning Albuminuria."

MICHIGAN.

Hospitals Opened.—The new addition to the Menominee River Hospital was opened October 2. The new building has accommodation for 20 patients and has also a well-equipped operating room.——The Northern Michigan Hospital, Calumet, reopened last week after having been closed for four months.

Personal.—Dr. Claudius B. Chapin, Benton Harbor, fractured his wrist October 2 while starting his automobile.——Dr. Charles C. Clancy, Port Huron, was thrown from his bicycle October 5 and sprained his left wrist.——Dr. John E. Clark, Detroit, has been made professor of medical jurisprudence in the Detroit College of Medicine.

Fraud Order Issued.—The postoffice department has issued a fraud order in the case of a Michigan concern which is alleged to have swindled numerous persons in Indiana and which was known under the names of the Adrian Medico-Surgical Institution, the Adrian Medical and Surgical Institution, and Dr. Durham's Remedy Company.

Third Councilor District.—The society for this district met at the Battle Creek Sanitarium October 18. The use of the operating rooms of the sanitarium was donated to the society for convenience in showing clinical cases. The clinic was held in the morning. In the afternoon the scientific session was held. Dr. David Inglis, Detroit, president of the state society, and Dr. A. P. Biddle, Detroit, secretary, were present. The Battle Creek Sanitarium tendered a vegetarian banquet to the members of the society and guests.

Mortality of Michigan.—The total number of deaths for September was 3,050, an increase of 253 over the preceding month. The death rate was 14.6 per 1,000, as compared with 12.9 for August. There were over 400 more deaths during September, 1905, than during September, 1904. There were 804 deaths of infants under 1 year, 257 deaths of children aged 1 to 4 years, and 789 deaths of persons over 65. Important causes of deaths were as follows: Tuberculosis of the lungs, 213; typhoid fever, 68; diphtheria, 22; scarlet fever, 4; measles, 3; whooping cough, 11; pneumonia, 65; diarrhea and enteritis of infants under 2 years, 527; cancer, 146; accidents and violence, 230. There was a slight increase in the mortality from typhoid fever and a very considerable increase in that from diarrhea of infants. There was only one death from smallpox during September and one death from tetanus.

NEW YORK.

Horses for Hospital.—Mrs. Clarence H. Mackay, who presented the Nassau Hospital at Mineola, L. I., with a stable, stable equipment and an ambulance, has added a gift of a valuable team of horses.

One Board Instead of Many.—The New York State Medical Association unanimously adopted resolutions advocating the establishment of one state medical examining board instead of three or more, as at present exist.

Charity Musicale.—Mrs. Edwin Gould gave this entertainment at Ardsley-on-the-Hudson, on October 6, where $1,000 was realized for the benefit of the Robin's Nest, a summer home for crippled children at Tarrytown, N. Y.

Buffalo Personals.—Dr. Edward R. McGuire returned from Europe.——Dr. Herman E. Huyd is at Aspinwall, Lenox, Mass.——Dr. Albert E. Wachnert has recovered from an attack of appendicitis.——Dr. Roswell Park has returned from Europe.

Wants Coroners Abolished.—Resolutions announcing the continuation of the coroners' offices, particularly in New York City, and asking for the abolition of the coroners' offices throughout the state were adopted by the New York State Medical Association at its meeting October 16.

State Association Election.—The election of officers of the New York State Medical Association resulted as follows: President, Dr. Allen Arthur Jones, Buffalo; vice-president, Dr. H. Ernest Schmidt, White Plains; secretary, Dr. Charles Ira Redfield, Middletown (re-elected), and treasurer, Dr. William G. Le Boutillier, New York City.

Amalgamation Wins.—At the meeting of the New York State Medical Association, October 17, Dr. W. R. Townsend moved and Dr. E. Eliot Harris seconded the resolution for amalgamation and for the continuation of the committee on conference with the Medical Society of the State of New York. The vote for amalgamation stood 1,517 to 2, with 295 not voting. The next step is for the committee to petition the court for an order amalgamating the association and the society, and this, it is hoped, will be carried through before January 1. It is confidently believed that the crowning feature of the centennial celebration of the state society may be its amalgamation with the state association and the long-deferred union of the medical profession of the state.

New York City.

Passengers Quarantined.—Three steerage passengers aboard the *Slavonia* were sent to Hoffman's Island for observation. They are suspected of having typhoid fever.

Ambulance Accident.—A trolley car bound for Coney Island ran into a Flatbush Hospital ambulance, killing the horse and smashing the ambulance. The ambulance surgeon and the driver escaped injury. This is the ninth ambulance accident in Brooklyn in five months.

Open Air Sanatorium.—The State Board of Charities has been asked to approve of the incorporation of the Long Island Open Air Sanatorium of Brooklyn, formed for the purpose of furnishing hygienic treatment for consumptives and to encourage the control of tuberculosis on Long Island.

Gift to Hospital.—The sum of $5,000 has been given to the Sydenham Hospital for the purpose of endowing three beds by the sons of M. Guggenheim.——Mrs. Isaac Guggenheim has given $700 for improvements in the maternity ward.——The Lyric Theater has been offered for a benefit performance for this hospital on November 25.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended October 7, 381 cases of tuberculosis, with 168 deaths; 198 cases of diphtheria, with 19 deaths; 97 cases of typhoid fever, with 14 deaths; 58 cases of scarlet fever, with 1 death; 52 cases of measles, with 2 deaths, and 12 cases of cerebrospinal meningitis.

Personal.—Dr. Harvey W. Wiley, chief of the Bureau of Chemistry of the United States Department of Agriculture, addressed the Medical Association of Greater New York, on the evening of October 9, on the use of chemical preservatives and coloring matters in food products.——Dr. William K. Draper arrived home on the *Kroonlond* October 10.——Dr. and Mrs. John A. Robinson sailed on the *Koenigen Luise* October 14.

Smaller Freshman Class.—The registration just closing in the Cornell University Medical College shows a decrease over the best of the previous years. The three advanced classes are somewhat larger than usual, but the first-year class, which hitherto has contained an average of about 130 students, this year has less than 120. Medicine at present does not seem as attractive a calling as business, although 85 per cent. of the graduating class last year obtained hospital positions, and the hospital graduate has undoubtedly a better chance of success than others.

Hospitals for the East Side.—The State Board of Charities has pending before it applications from five parties who wish to incorporate hospitals to operate on the lower East Side. The board passed a resolution that, while there is apparent need for the extension of suitable hospital facilities in that district, the incorporation of so many would lead to confusion of effort and undesirable results. The proposed incorporators were advised to confer with each other with a view of extending the facilities of the institutions already in existence or of uniting in one hospital corporation.

Water-Supply Report.—The special commission on the water supply has reported to the Board of Aldermen. It proposes to tap the Catskill and at a cost of $161,857,000 to build an aqueduct to this city capable of adding 500,000,000 gallons of water to the present daily supply. This would give the city enough water to care for all the increase probable until 1925. The lack of water in Brooklyn during the past summer was almost without precedent in the history of a large American city, and this commission has provided plans for the immediate relief for this locality by tapping some of the numerous underground streams of Long Island for temporary relief until the work of bringing water from the northern part of the state can be completed.

New City Sanatorium.—A tuberculosis hospital is being planned which is to be built in the central portion of Staten Island, where the city owns 130 acres of land. This location overlooks the Narrows and the Lower Bay and is the highest point on the Atlantic coast between Portland and the Gulf of Mexico. Dr. John F. Fitzgerald has inspected the tuberculosis sanitariums of New York and New England in order that all the newest ideas may be incorporated. The wards are to be arranged in the form of an arc in order to furnish the maximum sun exposures. The estimated cost of the work when completed is about $2,000,000, and there will be accommodation for about 800 patients. There is no connection between this sanatorium and that undertaken by the Health Department for the treatment of incipient tuberculosis.

OHIO.

New Hospital Departments Opened.—The Toledo Hospital opened a well-equipped *x*-ray room, an isolation hospital and a laboratory last week.

Red Cross Badges for Toledo Physicians.—The city clerk of Toledo is now issuing Red Cross badges marked "Toledo Physician," which gives physicians wearing them the right of way on the bridges of Toledo and access within fire and police lines.

Banquet to Dr. Rosenwasser.—A banquet was tendered Dr. Marcus Rosenwasser, Cleveland, October 5, on the occasion of his return from a year's study in Europe, by fifty medical men of the city. Dr. Rosenwasser will resume his connection with the College of Physicians and Surgeons as professor of gynecology.

District Association Meets.—The Tenth District Medical Association held its annual meeting at London, October 5. The following officers were elected: President, Dr. Albert J. Strain, London; vice-president, Drs. W. Stanley Samson, Lancaster, Jefferson B. Scearce, Chillicothe, and Anson S. Beckwith, London; and secretary and treasurer, Dr. John H. J. Upham, Columbus. The next session of the association will be held in Lancaster.

Hospital Notes.—Charity Hospital, Cleveland, has entered on the celebration of its fortieth anniversary. During this time 26,000 cases have been handled, the greater proportion of which have been gratuitious. During the last year 1,700 patients were cared for.——On October 8 the corner stone of the addition to the Good Samaritan Hospital, Zanesville, was laid with elaborate ceremony. The cost of the new building will be about $70,000.

Medical Staff Organized.—The board of the Ohio Soldiers' and Sailors' Home, Xenia, has created a consulting and visiting medical staff, which organized October 6 by the election of Dr. Clark M. Galloway, Xenia, as dean, and Dr. A. C. Messenger, Xenia, as secretary. The staff is made up as follows: Dr. Warren C. Hewitt, Xenia, resident physician; Drs. Frederick Forchheimer, Cincinnati, A. C. Messenger, Xenia, and Clark M. Galloway, Xenia, general medicine; Drs. George W. Crile, Cleveland, William J. Gillette, Toledo, L. E. Russell, Cincinnati, Robert C. Rind, Springfield, James F. Baldwin, Columbus, Samuel S. Wilson, Xenia, Benjamin R. McClelland, Xenia, and Lawrence H. Brundage, Xenia, general and special surgery; Drs. Robert Sattler, Cincinnati, and Pearle R. Madden, Xenia, eye and ear; Dr. Andrew Timberman, Columbus, nose and throat; Dr. William T. Corlett, Cleveland, dermatology; and Dr. Henry C. Houston, Urbana, pediatrics.

Personal.—Dr. Minor M. Jacobs, Hamilton, has resigned as a member of the city board of health.——Dr. T. H. Brannan, Canal Dover, was stricken with paralysis October 3.——Dr. Frank Young, Lorain, has been appointed trustee of the State Children's Home, Oberlin.——Dr. Harrie B. Martin, Springfield, has been elected president of the Society of American Physicians of Vienna.——Dr. Alfred P. Scully, Cleveland, has returned from Germany.——Dr. and Mrs. Jerome B. Thomas, Dayton, have returned after five years in the Philippine Islands.——Dr. Herman S. Rhu, Marion, has gone to Texas for the benefit of his health.——Dr. M. E. Mowen has resigned as a member of the East Liverpool Board of Health to accept the position of city physician made vacant by the resignation of Dr. William J. Taylor.——Dr. John Maglott has been elected health officer of Mansfield, vice Dr. Reason S. Boles, deceased.

PENNSYLVANIA.

Typhoid Fever.—Typhoid fever is still prevalent at Manticoke. The total number of cases reported up to October 11 were 371. Dr. Logan of the State Board of Health has been detailed to take charge of the typhoid fever epidemic at Archbald, where 39 cases had been reported up to October 10.

Fines for Preserved Meat.—The report of the Dairy and Food Commissioner for the month of September shows that the fines collected from violators of the pure-food laws aggregated $7,000. Almost this entire amount came from the sellers of preserved or adulterated meats. These fines exceed by $4,000 the total for any other month this year.

Reading Relief Statement.—The statement of the Philadelphia and Reading Relief Association for August shows an expenditure of $22,238.20, of which $11,300 was paid for deaths and $10,938.20 for disability. The number of deaths was 19, of which 9 were from accidents and 10 from natural causes. One thousand one hundred and thirty-one new cases were reported.

Philadelphia.

Vital Statistics for September.—The report of the Bureau of Vital Statistics for September shows that 1,566 deaths were reported, 2,487 births and 318 marriages.

Hospital Report.—The report of the Mt. Sinai Hospital for September shows that 63 patients were admitted to the wards and that 3,893 were treated in the various clinics.

Large Classes at University.—The total rgistration to date in the University of Pennsylvania aggregates 3,570. There are 570 students registered in the medical department as compared with 546 for the year of 1904-05.

Personals.—Dr. John L. Borsch has returned from a prolonged visit to Europe.——Dr. T. K. Hamilton, an ophthalmologist of Adelaide, South Australia, was the guest of Dr. L. Webster Fox last week.——Dr. and Mrs. J. William White have returned from Europe.

Bacteriologic Laboratory Report.—The mortality report of the Bacteriologic Laboratory of the Bureau of Health shows that 456 diphtheria cultures and 400 specimens from typhoid blood were examined; 808 specimens of milk were analyzed and 86 specimens of sputum were examined.

September Medical Inspection.—The report of the division of medical inspection for the month of September shows that 5,405 inspections were made excluding schools; 3,747 visits were made to the schools and 675 children were excluded from attendance on account of some illness. The inspectors ordered 407 fumigations, examined 8 patients for special diagnosis, collected 79 cultures for examination, administered 95 injections of antitoxin and performed 1,317 vaccinations.

Health Report.—The deaths from all causes for the week ended October 14 aggregated 368. This is a decrease of 36 from the previous week and a decrease of 46 from those reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 12; consumption, 39; cancer, 22; apoplexy, 18; heart disease, 40; acute respiratory disease, 33; enteritis (under 2 years), 22; appendicitis, 3; Bright's disease, 31; accidents, 15; and marasmus, 11. There were 171 cases of contagious diseases reported, with 12 deaths, as compared with 191 cases and 28 deaths in the previous week, showing a marked decrease. The city has now been entirely free from smallpox for eight months.

WASHINGTON.

Hospital Dedicated.—The new hospital of the Northern Pacific Beneficial Association at Tacoma was formally dedicated August 27. The building complete cost $100,000.

Typhoid at Penitentiary.—Typhoid fever is raging in the state penitentiary at Walla Walla, where 59 out of 755 prisoners are in the prison hospital. Before the epidemic appeared Dr. Yancey C. Blalock, the prison physician, repeatedly warned the warden of the danger, but nothing was done.

Sanatoria to Be Built.—Plans have been perfected for the erection of a health resort and sanatorium at Spring Beach, north of Seattle, to cost about $300,000.——Dr. F. M. Rossiter, North Yakima, has just completed the erection of a sanatorium in that city, which will be opened to the public this week.

Personal.—Dr. and Mrs. Augustus W. Thornton, Ferndale, recently celebrated their fiftieth wedding anniversary.——Fire in the Hutton building, Coulee City, destroyed the office of Dr. N. R. Gregg.——Dr. Landstrom, who was recently operated on for appendicitis at Seattle, is rapidly recovering from the operation.

Had No License.—C. Henderson, Lind, who issued a death certificate signing himself as a physician, was fined $50, September 1, for practicing medicine without a license.——"Dr." Mollison, Farmington, who was arrested September 23 on the charge of practicing medicine without a license, pleaded guilty, and was fined $50 and $8 costs.

Washington State Medical Association.—The sixteenth annual meeting of this association was held in Tacoma, September 27-29, under the presidency of Dr. James R. Yocum, Tacoma. The program included symposia on arteriosclerosis, the early diagnosis of tuberculosis, the digestive and nutritive disorders of children and infants, the prevention of infectious diseases, the early diagnosis of malignant disease, colic, dyspepsia and indigestion in adults, and organization of the medical profession, with an address by Dr. J. N. McCormack, chairman of the committee on organization of the American Medical Association. The election of officers resulted as follows: Dr. George W. Libby, Spokane, president; Drs. Lemon R. Markley, Bellingham, and Luther M. Sims, Kalama, vice-presidents; Dr. Curtis H. Thompson, Seattle, secretary; Dr. A. DeY. Green, treasurer; Dr. N. Fred Essig, Spokane, delegate to the American Medical Association; and Dr. James R. Yocum, Tacoma, alternate. The judicial committee for the coming year is composed of Drs. Charles G. Brown, Spokane; William C. Cox, Everett; Elmer M. Brown, Tacoma; R. N. Gordon, Seattle; Wilson Johnston, Colfax, and Nathaniel J. Redpath, Olympia. During the discussion of the organization it was announced that the population of the state was 874,310, that there were 967 physicians in the state, but 374 of whom were members of the state association. The next meeting will be held in Spokane.

WYOMING.

Personal.—Dr. Letitia Wiseman, Cheyenne, has become physician of Laramie County, succeeding Dr. William A. Wyman, whose term has expired.

Doctor Pardoned.—The State Board of Pardons on October 10, after a careful investigation of the case of Dr. Potts, Buffalo, now serving a term of twenty years for the murder of a man in a saloon at Big Horn, recommended that he be pardoned.

Robbed and Restored.—Dr. John H. Conway, Cheyenne, who had an envelope containing $5,000 worth of stocks and securities stolen from his safe September 28, and also $125 in cash, received an envelope the next day containing the non-negotiable stock and securities, but not the cash.

Sheridan Physicians Threaten Boycott.—The physicians of Sheridan have forwarded an ultimatum to the governor that unless he confines the work of the present medical director of the state hospital strictly to that institution, they will boycott the hospital and refuse to aid in its operation.

New State Hospital Overcrowded.—The new State Hospital at Sheridan, which was completed only four months ago at a cost of about $25,000, is already unable to accommodate the large number of patients who desire to enter the institution. The state auditor will furnish increased accommodation by providing quarters for the nurses in another building.

GENERAL.

Tri-State at Memphis.—The Tri-State Medical Association of Mississippi, Arkansas and Tennessee will hold its twenty-second annual meeting at Memphis, Tenn., in the Hotel Gayoso, Nov. 21-23, 1905. Further information may be obtained from the secretary, Dr. Richmond McKinney, Memphis, Tenn.

International Sanitary Conference.—The second International Sanitary Conference of American Republics was held in Washington, D. C., beginning October 10. Delegates from twelve South American republics, from the Army and Navy and from the United States Health and Marine-Hospital Service were in attendance. Surgeon-General Walter Wyman presided. The address of welcome on behalf of the government was made by Mr. Root, the secretary of state. Mr. Taylor, assistant secretary of the treasury, also welcomed the delegates on behalf of the Public Health and Marine-Hospital Service. The response was made by Mr. Quesada, the Cuban minister. The present quarantine arrangements were criticised and some modifications suggested. It was proposed to translate the U. S. Pharmacopeia to Spanish. This is to be reported on at the next meeting, which will be held in Mexico City in 1907.

Alvarenga Prize Award.—The 1905 prize has been awarded to Dr. Chalmers Watson of Edinburgh, Scotland, for his essay, entitled "The Importance of Diet; an Experimental Study from a New Standpoint." This prize is given by the College of Physicians of Philadelphia, and consists, each year, of the income of the bequest of the late Señor Alvarenga, amounting to about $180. The next award will be made July 14, 1906, provided that an essay deemed by the committee of award to be worthy of the prize shall have been offered. Essays intended for competition may be on any subject in medicine, but can not have been published. They must be typewritten, and must be received by the secretary of the college on or before May 1, 1906. Each essay must be sent without signature, but marked with a motto and accompanied by a sealed envelope having on its outside the motto and within the name and address of the author.

The Health of the Army.—In his official report for the year ending June 30, 1905, Surgeon-General O'Reilly states that there were 79,586 "admissions to sick report," 406 deaths from all causes, and 1,377 discharges for disability. He states that by far the most important diseases affecting the efficiency of the Army have been venereal, that the control of these diseases lies in the hands of the civil authorities, and that one of the most important steps to that end would be the classing of these with other contagious and reportable diseases. Notwithstanding that a large proportion of the Army was serving in the tropics there was no death or admission to sick report from snakebite. The report states that it is impossible to make any just comparison with the statistics of other countries, as in the United States the admissions include all soldiers who are excused from any part of their military duties, while this is not the case with any other country; that portion of the Army serving outside of the geographical limits of the United States is also included, while this is not the case with any other country except Great Britain. Some countries have a low death rate because their sick are promptly discharged or retired and die out of service instead of on sick report. The very high proportion of alcoholism in the American Army as compared with the British army is partly due to the fact that in the latter service only admissions to hospital are counted. While the British have less than half the American admission rate for dysentery their death rate is practically the same. The figures for measles and mumps compare very unfavorably with other armies with the exception of the French. The comparatively high American death rate from tuberculosis is explained by the fact that in the United States Army tuberculosis patients are sent to a sanitarium and retained in the service for long periods, while in other armies they are discharged. The undue prevalence of typhoid fever is explained by Dr. O'Reilly by its undue prevalence in civil communities where the troops are stationed as a result of the general failure in American municipalities to purify water and sewage.

Yellow Fever.—During the past week there has been a still more marked diminution in the number of cases at New Orleans. Further improvement in Louisiana and Mississippi is following the low temperature and frost, which, on October 12, reached to within thirty-five miles of New Orleans. Quarantines are being relaxed. Baton Rouge has opened its doors to the world. All the shotgun quarantines were abandoned on October 15.——Dr. L. Szabary, reported last week as arrested on two charges of neglecting to report cases of yellow fever, was fined the limit provided by law, but he appealed his case.——One New Orleans newspaper maintains there has been no yellow fever in the city. It is said that last week one of its reporters died of the fever and another is down with it.——In all there have been eight cases at Baton Rouge.——Patterson, La., is still suffering severely.——In New Orleans fumigation has ceased, and the emergency sanitary force has been discharged.——It is expected that by October 23 most of the quarantines will be raised.——The towns of Hamburg and Scranton, Miss., although infected, refused to take any steps against the epidemic and made it so unpleasant for the physicians who came to help them that the latter were forced to retire. The tales of the medieval ignorance of the people of these two towns are almost beyond belief.——It is reported that the authorities have gathered much sworn testimony of "grafting" on the part of local health officials throughout the yellow-fever zone. It is to be hoped that it will be used to secure exemplary punishment.——At Natchez there has been great trouble with people who would not permit fumigation and who obstructed all efforts at rational sanitation. A prominent citizen was tried for obstructing the health authorities, but the mayor set him free. Thereon the physicians, under the leadership of Surgeon Lavinder, United States Public Health and Marine-Hospital Service, met and decided on vigorous action. The city authorities then modified their attitude.——At Pensacola., Fla., the situation is improving, but it has been very bad. The British vice-consul died last week of yellow fever. Dr. H. H. Baulter, a dentist, wrote to the Atlanta *Journal* that there was no yellow fever in Pensacola. Fate overtook him, as he died of the fever on October 3. Nearly every section of Pensacola contains foci, but a vigorous fight against the infection has wrought improvement.——Arkansas has agreed to admit Florida oranges provided they come in screened cars.——Missouri has raised its quarantine, and St. Louis has ceased its inspection service.——The Illinois authorities, on October 14, suspended inspection at Thebes and Brookport, and it was announced that the Cairo quarantine would be raised October 17.——A fatal case of yellow fever occurred at Marion, Ind., the victim being a refugee from Louisiana.——A good deal of yellow fever is reported at Puerto Barrios, Guatemala.——In Mexico there is yellow fever at Tuxtepec, Vera Cruz, and Tezompa.——Up to the first of October it is figured that in New Orleans one person out of every 102 had had yellow fever and that one out of every 792 has died of it. The figurer went further and estimated that in a two days' visit President Roosevelt will run one chance in 3,890 of contracting the fever and one in 29,000 of dying of it.

CANADA.

The Montreal League for the Prevention of Tuberculosis.—This league has established a new home, Brehner Rest, at Ste. Agathe, fifty miles from Montreal, for patients in the pretuberculous stage. Dr. A. J. Richer, Montreal, is the physician in charge.

Montreal's Mortality.—Four thousand nine hundred and fifty-two persons died in Montreal in 1904 among the French-Canadian population; 2,855 were children under 5 years, 294 from 5 to 20 years, 1,348 from 20 to 70, and 145 over 70 years. There were 76 deaths in Montreal during the week ending October 7. Of this number 31 were of children under one year.

Ontario Board of Health.—Dr. Hodgetts, secretary of the Ontario Board of Health, has called a meeting of the board to discuss various plans for sewage disposal in connection with different towns in Ontario. The board is directing the attention of lumbering companies to the fact that a regulation of the department calling for medical men in all lumber camps must be complied with.

Annual Meeting of the Winnipeg Medical Association.—The annual meeting of the Winnipeg Medical Association was held in the medical library October 6, when the following officers were elected for the ensuing year: President, Dr. Gordon Bell; first vice-president, Dr. E. W. Montgomery; second vice-president, Dr. J. R. Davidson; secretary-treasurer, Dr. Charles Woollard; executive committee, Drs. Mary Crawford, Hugh MacKay, A. D. Carscallen and N. J. McLean.

Personal.—Dr. Bruce L. Riordan, Toronto, surgeon to the Grand Trunk Railway, has been appointed division surgeon of the middle, northern and southern divisions of that railway in Ontario.——Dr. D. King Smith, Toronto, has returned from a trip to England.——Dr. E. R. Frankish, Toronto, has gone to trip to England.——Dr. E. R. Frankish, Toronto, has gone to the hospitals of London and Dublin.——Dr. Coote of Quebec has reported to the government of the province of Quebec that trachoma is prevalent along the line of the Quebec & Lake St. John Railway.——Dr. G. W. Elliott of the immigration department of the Canadian government has just been appointed Canadian medical inspector at Ellis Island, New York.——On behalf of the practitioners of Winnipeg Dr. H. H. Chown recently presented Dr. Chestnut of that city with a handsome cabinet of silver.

Hospital News.—During the week ending October 14 an additional $22,000 was subscribed to the Toronto General Hospital.——Three hundred and seventy-five patients were treated in the Winnipeg General Hospital during the week ending October 7; of these 271 were men, 69 women and 35 children; 97 outpatients were also treated.——Dr. Charles Doherty, superintendent of the British Columbia Provincial Hospital, states that there were 353 inmates in that institution on September 1; that 11 were received during September, and that 1 died. There were 362 in the hospital on September 30, 1 being discharged on probation.——The Western Hospital, Montreal, recently received a bequest of $2,000 from the late Mr. W. S. Evans.——Additional accommodation has been arranged for typhoid fever patients at the Winnipeg General Hospital. So far the death rate is low for the number of cases reported.——The new Alexandra Infectious Diseases Hospital in Montreal is nearing completion, but $150,000 is yet needed to carry out the plans of the trustees successfully. One hundred and twelve beds will be required for the three wards, for diphtheria, scarlet fever and measles.

FOREIGN.

Nestor of Russian Pharmacists.—Prof. J. Trapp, professor emeritus of pharmaceutics at the St. Petersburg Military Academy, celebrated his ninetieth birthday in September.

Osler to Lecture.—Dr. Osler, according to the *Medical Press*, has accepted the post of Thomas Young lecturer on medicine at St. George's Hospital, London, and will give a series of lectures and demonstrations at the hospital next spring on the diagnosis of abdominal tumors.

Plague in Australia.—A fatal case of bubonic plague occurred at Townsville on August 4. The patient, a boy aged 13, was employed in a chemist's shop and lived on board a coal hulk moored at the wharf. Several plague infected rats were found on the wharf. Two plague patients are under treatment at Cairns.

Dengue in Cuba.—Acting Assistant Surgeon Nuñez reports that the epidemic of dengue in Matanzas continues to spread. No prophylactic measures of any kind are being observed against its dissemination, in view of the fact that the disease is assuming a benign form and that no deaths have been reported. Some cases of dengue have been reported from Limonar near Matanzas.

Care of School Children in England.—The annual report of Dr. Davies, the medical officer of health in Bristol, states that there are 65,000 children in the schools in that city and that there is urgent need for their medical inspection. The London board of education has a medical officer and is preparing a scheme of inspection. Blackburn, Leicester and Liverpool are also moving in the matter, and Dr. Davies in his report states that if Bristol took some action it would not only be a wise measure from the viewpoint of public health, but would also prove a saving in taxes.

Yellow Fever in Central America.—It is reported that yellow fever, or a disease closely akin to it, has made disastrous progress during the last few months in the lowlands on the Atlantic slope. While it is difficult to get at the facts, there seem to have been several deaths in towns situated at some distance from each other. The situation is reported to be particularly deplorable at Zacapa and Gualan, on the Guatemala Northern Railroad. This railroad has been compelled to close construction camps nearest to the infected region; mail trains only are operated. Several deaths from yellow fever in the American colony have been reported.

Petition to Legislature of Argentine Republic.—A bill is now pending in the Argentine legislature which aims to protect the interests of the medical profession. The physicians and medical students throughout the land are intensely interested in the passage of the bill. A petition asking for immediate action on the bill and its acceptance, with such modifications as experience may suggest, is to be presented to the chairman of the house of deputies. The petition has been kept at the office of the *Semana Medica* at Buenos Ayres, and more than a thousand signatures had already been received by September 1, the date of the last issue of the *Semana* that has come to hand.

Sanitation in Manchuria.—According to *Public Health Reports*, there has been earnest and hearty co-operation in Niuchwang between the Japanese military administration and the consular body in providing strict quarantine regulations. In the enforcement of this, together with all regulations governing the native Chinese city, the military administrator and his staff have conducted all the executive functions and are justly entitled to the credit, as under military occupation they would have been blamed if they had neglected to provide sanitary precautions and an epidemic had followed. Under Russian occupation, both cholera and plage infested Niuchwang at times, although the Russians, under a civil administration, also battled with uncleanliness and initiated quarantine regulations. Although they were not successful, cholera having made its appearance in 1902 and bubonic plague in 1903, still the pioneer sanitary campaign of the Russians in the native city blazed the way, as it were, notwithstanding that the immediate beneficial results were uncertain. The loss from cholera in 1902 being only 1,013, and in the year 1903 from plague only 890, indicates that the precautions taken served to check the spread of the dreaded epidemics. It is believed by the port physician that Niuchwang will be fortunate enough to pass the season without the appearance of any epidemic. The whole Chinese district of Niuchwang is scoured and cleaned with the regularity of clockwork. Twenty Japanese, from the medical staff down, are specially detailed on the service. They employ sixty Chinese and as many Chinese carts. The district is divided into three sections. In each section every morning a physician sets out on his daily round from door to door. Two gendarmes go with him. It is his first duty to find out if any fresh cases of illness have appeared. He has to see at the same time that the premises are cleaned well, that filth and dirt are put in their right place, and that the refuse matter is gathered in the garbage box provided for the purpose. The cleaning force follows, with its train of twenty Chinese carts. A Chinese policeman takes the lead. Bell in hand, he keeps ringing the bell, as if the welfare of all Niuchwang depended on it. The people within hearing are reminded of the appearance of the procession. The contents of the garbage box must be emptied on the carts. This is paramountly positive. When the carts are loaded well, or have taken over what there was to receive, they start on a march out of the mud wall to the dumping ground, or rather dumping hollow. Earth is thrown over the heap to cover it up. Meantime the disinfecting force of seven has taken its turn. A medical expert is of the number. He has gone over the reports of the inquiry force for the day, and can tell what particular points await his call. He has marked out the day's round before he sets out. Disinfectants are liberally applied when necessary. The fresh cases of illness, if there be any, are examined and their nature is ascertained.

LONDON LETTER.

Increase of Lunacy.

The fifty-ninth annual report of the commissioners in lunacy has just been issued and again shows an increase in the prevalence of lunacy in the population of England and Wales. The number certified as insane on Jan. 1, 1905, was 119,829, being an increase of 2,630 on the number for the previous year. This increase for 1904 may be compared with those of 3,235 for 1903, 3,251 for 1902, and 2,769 for 1901. The average annual increase in the ten years ending December, 1904, was 2,575, and in that of the five years ending on the same date, 2,644. The increase in 1904 thus exceeded the average annual increase in the ten years by only 55, and was less than that in the five years by 14. On Jan. 1, 1905, the total number of certified insane in England stood to the estimated population in the proportion of 1 to 285, or 35 per 10,000—an increase of 1.09 per cent. on the ratio for the same day of the previous year. In 1896 the ratio was 31.3, so that it has increased by 12 per cent. in the past nine years. The commissioners direct special attention to alcoholism as one of the causes of the increase of lunacy. In the five years 1899-1903 it was an assigned cause of insanity in 22.7 per cent. of the male admissions to asylums and in 9.4 per cent. of the female.

Scalp Isolation in Ringworm in School Children.

At the Congress of Public Health, recently held in London, Dr. David Walsh described an ingenious method of treating ringworm of the scalp which enabled the child to attend school—a thing which at present is impossible except in large cities where special schools for children suffering from ringworm are provided. The advantages of the method are great if the great loss of education which the intractable nature of the disease entails be considered. The scalp is first shaved, no matter whether there be one patch of ringworm or many; it is then rubbed with turpentine, washed with soap and water, and dressed with a germicide, such as a weak solution of formalin or sulphurous acid. It is then exposed to the *x*-rays for ten minutes, and finally it is painted with several coats of flexible collodion containing 10 per cent. of salicylic acid. The use of the *x*-rays is not essential; a mild irritant application may be substituted for it. In the next few days a fresh coat of collodion is applied, especially if there is any tendency of the collodion cap to crack. If desired, the cap may be strengthened with a coating of rubber solution, with Unna's zinc-gelatin, with a thin layer of cotton wool, or with strips of rubber adhesive plaster. After a week or days the cap is forced up one-eighth of an inch by the growth of the hair. It can then be gently stripped off, bearing on its under surface the firmly adherent stumps of diseased and healthy hairs. If it can not be stripped off without causing much pain its removal may be rendered easier by inserting a pair of scissors and snipping some of the hairs. The ringworm hairs are twisted and irregular as they were on the scalp, and some of them are turned white, presumably from the action of the ether in the collodion. The process may be repeated as often as necessary. An objection to the treatment is that collodion is somewhat costly, but no doubt cheaper substitutes, such as rubber solution, may be found.

Scarlet Fever in London.

For some weeks the officials of the Metropolitan Asylums Board have been coping with one of the most serious outbreaks of scarlet fever which has occurred in London for some years. It is now thought that the outbreak has passed its maximum stage, though according to the last report over 100 patients have been removed from their homes in one day. There are now under treatment in the fever hospitals 4,228 cases. The disease is scarlet fever in 3,404, diphtheria in 685 and typhoid fever in 138. Scarlet fever is prevalent in all parts of the metropolis.

Correspondence

Medical Reciprocity.

Dallas, Texas, Oct. 5, 1905.

To the Editor:—The student of European history, no doubt with an amused smile on his lips, has frequently read about the ridiculous and petty conditions that existed in Europe, especially in Germany, in bygone centuries. A number of small principalities and duchies existed then along the Rhine and in the German empire, and with incredible jealousy and hostility those petty monarchies watched over their prerogatives and rights and surrounded themselves with a barrier of tolls and taxes that made trade and travel only too difficult. The Napoleonic wars, the revolution of 1848 and the German-Austrian war of 1866 swept those little principalities away and in their stead we find a German nation, a united German empire. Before the emancipation of Alexander the Second, the Russian peasants were tied to the soil, to the place of their birth, and the Russian Jews, even at the present time, with certain exceptions, are kept within a certain district, the so-called "pale" of Russia. The American people are proud, and have a right to be proud, of their country, of the vast progress it has made and of the success of the doctrines promulgated by its founders. Every artisan or every mechanic, every tradesman, born in Alaska or Florida, whether he has worked in Maine or California, under the privileges granted him by the Constitution of this country, has a perfect right to leave his abode, to go wherever he pleases and to start his work again, without interference from any authority.

This rule, however, does not seem to hold good for the medical profession of the country. The restrictions placed by the different state boards have practically made the physician a slave to the place and state he happened to locate in. There is no denying that these restrictions were well meant and were made for the benefit of the people and for the benefit of the honorable and honest members of a noble profession. While they were drawn apparently to protect the public against the importunities of the quack and the itinerant vendor of medicine and to protect the better educated, better trained part of the profession from the vast army of ill-prepared, untrained graduates of third-rate colleges, these rules work untold hardships on a number of good, honorable members of the profession. It is a difficult matter for a physician to settle in a new locality when broken-down health, lack of congeniality, of scientific instruction and a number of other factors compel him to take this step and to commence work again in a strange community. At the outset he is confronted with the difficulty of an examination before a state board. The demands of active practice, the strenuous life the physician leads, the demands of his family and the financial part of his practice, in the course of years, have made him forget the exact number of blood corpuscles to the square inch, or the exact origin of certain nerves or muscles, or the different effects of certain drugs which have become obsolete. Yet that very same man has, perhaps, lived and worked in a community for many years as a respected and beloved physician. He may have helped to build up a city and have been a useful member of society; in short, he may have been a good man in every respect. Still, should he decide or be compelled to change his place of abode, he is confronted at the outset with the insurmountable barrier of an examination before a state board.

The situation is extremely unfair. A physician in Germany can change his location from West Prussia to Bavaria without any trouble; a physician practicing in Ems in summer may practice in Italy or the Riveria during the winter*; but let any physician, let us say from Mississippi, visit a summer resort in Colorado or Michigan and dare to prescribe for a friend or acquaintance, would not the state board swoop down on him and haul him into court? Ours is one country, with one language, and those measures of protection, originally well meant, are certainly an injustice to and a burden on many physicians.

Many progressive and enlightened members of the profession have already mentioned this anomalous condition in the medical press of this country, and the efforts of some state boards in accepting certificates from certain states as an exchange of courtesies, is, indeed, a step in the right direction, but there is still plenty of room for improvement. In my opinion, a physician who contemplates a visit to some health resort for a month or two should be allowed to practice there on a temporary license. A physician who is compelled to go to another state should be permitted to practice if he produces a properly signed certificate of his county and state society, like a church letter attesting his moral and professional qualifications.

William Osler, in his Farewell Address (The Journal of A. M. A., Aug. 9, 1905, page 366), says: "A few months ago a man who is registered in three states, an able, capable practitioner of twenty years' standing, a hard student in his profession, a physician who has had charge of some of the most important lives of this country, had to undergo another examination for license." What an anomaly! What a reflection on a united profession!

Emile Aronson, M.D.

The Proportion of Night Labors.

Davenport, Iowa, Oct. 14, 1905.

To the Editor:—In The Journal of this date you refer to White, who considers the idea that a majority of labors terminate at night as probably fallacious and suggests a further consideration of statistics.

In the *Medical News*, Sept. 12, 1891, Dr. G. W. H. Kemper recorded the statistics of 1,000 consecutive cases, 13 of which were twins, the hour of two births not recorded, leaving a total of 1,011 births. Dividing the day into six-hour periods beginning at midnight, there were in the first 291, in the second 267, in the third 222, and in the fourth 231 births, being an excess of 33 in favor of the night hours.

Of the 250 consecutive labors of which I have kept notes 81 terminated in the first quarter of the day, 68 in the second, 43 in the third and 58 in the fourth, being an excess of 28 in favor of the night hours.

In both series there is a decided maximum between midnight and 6 a. m., and I believe that it will be found that this generally holds good.

C. H. Preston.

"The Mosquito Theory in Text-Books."

Philadelphia, Oct. 16, 1905.

To the Editor:—The criticism of Dr. McCaw [The Journal, *Oct. 7, 1905*, p. 1100] is correct, and I am very much obliged to him for calling my attention to an obvious oversight, which escaped me in the revision, owing to the pressure of many duties. I wish also to thank Major Kean, surgeon, U. S. A., for noting the error to me simultaneously. The profession has been good enough to call for a new printing, which is in progress, and I have taken this opportunity to make the necessary correction.

J. H. Musser.

---

* We feel sure that our *correspondent* is misinformed as to these statements.—Editor.

Marriages

W. A. West, M.D., to Miss Marion Cottrell, at Richmond, Va., October 3.

Richard Lee Gill, M.D., to Miss Tillie Fehsenfeld, at Baltimore, October 11.

Roy H. Elliott, M.D., to Miss Gertrude Vance, both of Connersville, Ind., October 18.

Aubrey Posey, M.D., to Miss Katherine E. Howard, at Chapel Point, Md., October 5.

John C. D. Davis, M.D, St. Michaels, Md., to Miss Bertha Beck, at Baltimore, October 6.

J. Philip Gibbs, M.D., to Miss Mary Brent McAshan, both of Houston, Texas, October 18.

Eugene Towner Senseney, M.D., to Miss Miriam Coste, both of St. Louis, October 18.

George William Fox, M.D., to Miss Marguerite Romadka, both of Milwaukee, October 18.

Charles E. Parker, M.D., Sterling, Ill., to Miss Stella Geoffroy of Rock Falls, Ill., October 5.

Frederick S. Bootay, M.D., New York City, to Miss Edna G. Cavalier, at Baltimore, October 4.

Lancelot Ely, M.D., Flanders, N. J., to Miss Alice Louise Lawrence of Dover, N. J., October 10.

Samuel Patten Ames, M.D., to Miss Lotta Marie Smiley, both of New York City, September 30.

Newell Simmons Ferry, M.D., Memphis, Tenn., to Miss Caroline Taylor of St. Louis, October 14.

Howard Pennel, M.D., Downingtown, Pa., to Miss Hannah S. Mellor of West Chester, Pa., October 11.

William Allen Turner, M.D., Newman, Ga., to Miss Annie Kirk Dowdell of Opelika, Ala., October 18.

John Alexander Robinson, M.D., New York City, to Miss Grace A. Bergfels of Newark, N. J., October 12.

Perry B. Goodwin, M.D., Summum, Ill., to Miss Mabelle B. London of Bristol, Conn., at Astoria, Ill., October 3.

John L. Myers, M.D., Shepherdstown, W. Va., to Miss Nannie Van Metre of Berkeley County, W. Va., October 6.

Deaths

Eugene P. Bernardy, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1868, of Philadelphia; for several years connected with the teaching staff of the University of Pennsylvania and at one time visiting obstetrician to the Philadelphia Hospital; a member of the Philadelphia County Medical and Philadelphia County Obstetrical Societies, and also of the Medical Society of the State of Pennsylvania and the American Medical Association, died in Atlantic City from Bright's disease, October 11, aged 58.

Frank Buller, M.D. Victoria University, Coburg, Ont., 1869; McGill University, Montreal, 1876, died October 11 at his home in Montreal, aged 61. For seventeen years he held the post of ophthalmic and aural surgeon to the Montreal General Hospital, but resigned a few years ago to accept the same position at the Royal Victoria Hospital. He was one of the most noted oculists of America, and his recent researches in conjunction with Dr. Casey A. Wood, Chicago, on the effects of wood alcohol will be remembered.

William P. Tonry, M.D. Baltimore Medical College, a mining and chemical expert, formerly connected with city and state boards of health, died at his home in Baltimore, October 3, from angina pectoris, aged 64. He was an A.B. of Boston College, and a Ph.D. of Georgetown University. For three years he was in the laboratory of the surgeon-general's office, United States Army, and for several years held the chair of chemistry in different colleges

Alonzo Morris Buck, M.D. University of Georgetown Medical Department, Washington, D. C., 1866, hospital steward during the Civil War; since that time an employé of the War Department and at the time of his death chief clerk of the sanitary and disbursing division of the surgeon-general's office, died at his home in Hyattsville, Md., September 29, after an illness of several months, aged 79.

Decatur Curran Ande[illegible], M.D. Tulane University of Louisiana Medical Department, New Orleans, 1901, of Moss Point, Miss.; formerly representative of the Louisiana State Board of Health in Central America, who on the outbreak of yellow fever at Tallulah, La., volunteered his services, died from the disease September 27, aged 28. The local chapter of his fraternity passed resolutions of respect to his memory.

Molton E. Hornbeck, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1865, for forty years local surgeon for the Lehigh Valley Railroad; a member of the Lehigh Valley Medical Society and the Medical Society of the State of Pennsylvania, died at his home in Catasauqua, Pa., October 9, from cerebral hemorrhage, aged 63.

Ellery Channing Clark, M.D. University of Vermont, Burlington, 1860, surgeon of the Eighth New Hampshire Volunteer Infantry in the Civil War, several times wounded; who was examiner in the United States pension office, Washington, until 1902, when he retired, died at his home in Baltimore October 3, after a lingering illness, aged 69.

Carl Seiler, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1871, formerly of Philadelphia, for twenty years a member of the faculty of the university, died at his home in [illegible]er 10, aged 56. He was a member of the [illegible] County and Lackawanna County Medical Societies.

Joseph R. McOscar, M.D. Ohio Medical University, Columbus, 1896, of Waterville, Ohio, a member of the American Medical Association and the Northwestern Ohio Medical Association, died from acute mania at St. Elizabeth's Hospital for the Insane, Washington, D. C., October 6, after an illness of three weeks, aged 41.

Edgar S. Hooper, M.D. Rush Medical College, Chicago, 1895, a member of the American Medical Association, Wisconsin State Medical Society, Central Wisconsin Medical Society and Lafayette County Medical Society, died recently at his home in Darlington, Wis., after a long illness from tuberculosis, aged 36.

Reason S. Boles, M.D. University of Wooster Medical Department, Cleveland, Ohio, 1869, a pioneer physician of Richland County, Ohio, health officer of Mansfield, died at his home in that city October 3 from neuralgia of the heart, after an illness of less than forty-eight hours, aged 62.

Thomas Addison Jenkins, M.D. Bellevue Hospital Medical College, New York City, 1897, who has been residing in Denver for the last four years, died from consumption at the home of his brother in Brooklyn, N. Y., October 11, aged 33.

Joseph B. Jones, M.D. College of Physicians and Surgeons in the City of New York, 1855, at one time coroner of Kings County and health commissioner of Brooklyn, died at his home in Brooklyn, October 9, aged 77.

Eli Ayer Chase, M.D. Long Island College Hospital, Brooklyn, N. Y., 1872, while despondent from ill health, committed suicide by shooting himself through the head at his home in Brockton, Mass., October 3, aged 58.

Stephen Lett, M.D. Toronto University Medical Faculty, 1879, of Guelph, Ont., died October 11 in the Homewood Retreat, Guelph, an institution over which he presided ably several years ago, aged 58.

John A. McKenzie, M.D. College of Physicians and Surgeons, Boston, Mass., 1892, assistant superintendent of the Provincial Hospital for the Insane, Halifax, N. S., since 1893, died in Halifax, October 12.

James E. Baker, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1881, a retired practitioner of Lancaster, Pa., died at his home in that city, September 29, aged 52.

Wilson T. Bassett, M.D. Albany (N. Y.) Medical College, 1844, one of the most prominent practitioners of Otsego County, N. Y., died at his home in Cooperstown, October 3, aged 84.

Lawrence O. Wood, M.D. Cincinnati, 1899, of Madisonville, Ky., died at Deaconess Hospital, Louisville, October 15, following an operation for appendicitis, aged 35.

Samuel C. Allaband, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1865, died at his home in Philadelphia, September 21, aged 62.

Upton A. Sharretts, M.D. Pennsylvania, 1883, formerly of Frederick, Md., died at Colorado Springs, Colo., October 8, from hemorrhage of the lungs, aged 47.

James C. McCallister, M.D. Castleton (Vt.) Medical College, 1850, died recently at his home in Genoa, Ill., aged 90, and was buried September 27.

Morris Wiener, M.D. University of Berlin, Germany, 1839, author, editor and litterateur, died at his home in Baltimore, October 12, aged 94.

Miscellany

Fifty Annual Mineral Water Courses.—Carlsbad has recently celebrated the silver jubilee visit of one of its guests, a Moravian manufacturer, who returns year after year to take a course of the mineral waters at this health resort. His first visit was in 1828, when he was brought there in his tenth year on account of a kidney affection. His fiftieth resort to the Carlsbad springs this year was greeted with much ceremony by the town authorities, and the mayor announced that one of the walks is to be named after him, the "Proskowetz *promenade.*"

Medical Ethics.—The remedy for existing defects and evils in our ethical system does not depend on ironclad, written nor specific rules of conduct, nor on the strict observance of such principles of ethics generally accepted as proper and necessary. We have at the outset accepted the philosophic statement that a code of perfect personal conduct can never be made definite. This is easily accounted for by changing conditions, unusual exigencies and emergencies, the evolution of thought, action and ideas, and the kaleidoscopic nature of our daily lives. Character must be the foundation on which ethical action is to be built. Proper conduct among men and affairs must be left to the man, his tact, his judgment, his education and his experience. The ranks of the medical profession must be recruited from men of broad minds, of high ideals, of lofty purposes, of enlightened thought, of charitable tendencies and of honest intentions. This is the remedy for the defects in our ethical system and when this is accomplished, the medical profession will be what it should be: a common brotherhood working harmoniously for the common welfare of humanity; dispensing charity to all, rendering pain less poignant, suffering less acute, encouraging the depressed and the despairing, making the world better and brighter and life more worth the living.—Frankle, in *Denver Medical Times.*

Danger of Excessive Water Drinking.—In the *Blätter für Volksgesundheitspflege* of Berlin, Dr. K. Beerwald says that "there are few more positive feelings than that of thirst. While we may go for weeks without food, in a few days without drink men become desperate. This fact is easily comprehended when we consider that 63 per cent. of the body is water, and that we give out each day a large amount of fluid through the lungs, skin and excretions. However, we need to drink relatively very little fluid, as our food is to a large extent water, even dry bread being 40 per cent. water, while juicy fruit contains 80 per cent. On the hunt, mountain tour, or walk, those people have the most endurance who do not stop at every inn, who do not drink from every spring. And it is rather an indication of bodily weakness if these exercises produce excessive perspiration and extreme thirst. These two things are simultaneous, the one causes the other; the one who perspires a great deal drinks a great deal, and again, because he has drunk he perspires: Thus the body becomes a distilling apparatus, but it should be borne in mind that the work performed has a great deal to do with the causation of weakness and exhaustion. Excessive water drinking not only produces temporary disturbance, it also creates direct organic disorders; the heart and kidneys are particularly affected by the excess, and in these cases the vascular system is overcharged and the heart and kidneys overworked. Proof of such a condition is frequently seen in cases of slight injury. A man who suffers frequently from thirst bleeds easily, and we may well consider that excessive thirst is a sign that the amount of fluid in the body is not kept within bounds, and that this condition must be remedied by opposing the feeling of thirst. We do not mean, however, that on hot days it is not natural to have a more positive feeling of thirst than at other times. When the high temperature takes from the body its fluids we must supply their loss. But even in this case nature has supplied us with abundant fruits, and these should be the first things with which we seek to satisfy our thirst. If, however, one must drink, the best thing is water, or better still, water and lemon juice, or occasionally a glass of milk. We should never drink beer or alcoholic drinks, which only exhaust and tire. It is certainly not a blessing for the fatherland that beer has grown to be the national drink of the Germans."

Professional Lawlessness.—Let us admit that toward all sorts of notification required by law, physicians are more or less indifferent and exercise a discretion that is somewhat excessive and dangerous, even for men as wise and good as the best of them are. The law requires of physicians three sorts of notification—one relating to deaths, another to births, and a third to certain infectious diseases. Deaths are certified by physicians wherever the law forbids interment of a dead body before the fact and circumstances of death have been recorded. Where bodies may be buried without a permit, there deaths are not registered, and where burial permits are not required, there the people, including often the sanitary authorities, reject the advice of the medical profession, which has for 60 odd years maintained that the fundamental requirement of a sanitary administration is a complete and accurate account of current mortality. This is no defense of physicians. It is a charge of ignorance, wilful ignorance, against all the people of all but ten of the States comprising this Union. Physicians do not register births in the United States, though they know that a satisfactory statement of profit and loss in population cannot possibly be made without complete information as to the sources of damage and repair. Not one state, not one city, in this country can state a reliable birth-rate for any year, though hundreds of physicians regularly register the births occurring in their practice. Here again physicians are not defended, but the people of the United States, without distinction of locality, are charged with a remarkable lack of intelligence in conditioning more than a score of important privileges and immunities on the attained age of the citizen, without mentioning in any law the simple document upon which proof of age attained may rest.—*American Medicine.*

Blunders in English.—We sympathize with our contemporary, *American Medicine*, in the following complaint: The contributor who headed a paragraph, "A Case of Anthracosis," and reported a case of anthrax—well, his etymology was better than his pathology! There is scarcely a report or text-book published which does not use the words *case* and *patient* as synonymous—"the case recovered, died," etc., and the trials of the editor with manuscripts which repeat that "the case had no temperature," etc., are hard to bear. In a text-book on nervous diseases the word is further abused in the expression, "the case cured through stretching of the plantar," "the case was awakened by a rat running across the bed." The authors are not seldom most imperative that "my manuscript shall not be changed in any way"—at least for the better. In a much-used text-book a paragraph in large caps is entitled: "TO DISTINGUISH CHICKEN FROM SMALL-POX," and that sort of scientific, zoologic, or grammatic diagnosis reappears in most of our journals. Even this amusing nonsense is surpassed by another title in the same book, reading: "TO ELIMINATE THE KIDNEYS." In a well-known text-book, the author within half a page speaks of himself as "we," "I," "the author," "the writer." When he has to quote another, one can never know to whom the term, *the author*, or *the writer* (absurd in speaking of one's-self) refers. It is of course to be expected that this author should write:

"The sexual bladder."
"A sequelæ."
"Malformations is a congenital *hernia, etc.*"
"Cerebellar gait exists."
"Diagnosis is between this disease and migraine."
"*Hysterical joint* is a rigid, tender joint."
"A hallucinatory expression *of ants creeping* over the body."
"Astasia-abasia is inability to stand or sit well in hysteria."
"Diagnosis should not be confounded with other diseases."
"Nerve-energy is, *to my mind*, but the most refined form of electricity."
"*The* physiological mechanism in somnambulism is out of kilter, so to speak."
"Excision of the ganglion is to be had." "cure *will be had*, etc."
"*Early adult life* is [illegible] of neuralgia."
"Neuralgia is *more* [illegible] sex."
"Insomnia is someth[illegible] and is given to those conditions of insufficient or restless sleep or to the entire absence of sleep for a *long time*."
"Headache is a condition of *pain in the head*."
"*There* is no department of neurology more neglected than a proper understanding, or at least, if appreciated, the neglect of sufficient advice to *convalescents* from serious disorders of the nervous system, and in this place we shall devote *especial* consideration *to functional diseases*, those so considered in the absence of accurate scientific data to throw the light of a definite pathology upon many cases of them."

Pharmacology

Which Is It, a "Proprietary" or a "Patent" Medicine?

On the opposite page is a photograph of a full-page advertisement from the *Standard*, one of the leading London dailies. The page of the *Standard* is larger than that of any American newspaper, the space occupied by the advertisement being 18 inches by 24 inches. We have an assortment of advertisements of Kutnow's powder clipped from English newspapers, showing, as our correspondent who sent them remarks, that this is one of the best advertised "patent" medicines in England. In this country it is one of the most widely advertised "proprietary" medicines, as will be noted by a reference to our medical journals. We had to reduce the advertisement to get it down to our page limit, and part of the matter is hard to read without a magnifying glass. We have a variety of literature that would make interesting reading, had we space for it; but that included in the advertisement is sufficient to show what a wonderful remedy, according to the manufacturers, is this Kutnow's powder. It will be noticed that the testimonials from physicians—four of the six, we are proud to notice, are Americans[1]—are separated from those of the laity. This is wise, as the two do not mix well.

N. B.—We do not charge anything for inserting this advertisement.

Protest Against Paid Writeups.

One of the most discouraging phases of the proprietary medicine question is the fact that there are so many physicians who are ready to write up proprietary preparations favorably—but never unfavorably—for other than purely scientific reasons. There can be no objection to a physician writing and publishing an article on an ethical, strictly non-secret proprietary preparation, provided it is done with absolutely honest motives. We regret to say, however, that there are few of such articles written—so few that when one is presented it is looked on with suspicion. This abuse and species of graft is more prevalent in this country than in any other for well-known reasons, but medical journalism in Germany—and France also, to but slightly less extent—seems to be seriously affected by the same curse. Certain medical journals, judging from their contents, are published solely for the purpose of exploiting proprietary articles, and many of our German exchanges seem to have joined in this species of graft. Hence, it is not surprising that there has developed an opposition among the physicians there, as is noticed in a recent number of the *Muenchener medicinische Wochenschrift*. This journal states, September 26, that a petition with numerous signatures is being circulated, to present to the medical chambers (Aerztekammer) throughout Prussia, the purpose of which is to abolish the fraudulent practice of paid medical testimonials to the products of manufacturing chemists. The editorial continues:

"This fraudulent practice is, as is generally known, a by-product of our luxuriantly flourishing drug industry. The surest way to introduce a new drug to physicians is to have it scientifically recommended in the medical press. As a recommendation of this kind can not be obtained for every new remedy, many of the manufacturing chemists—and some of the most reputable firms among them, unfortunately—accomplish their purpose by paying physicians to write up apparently scientific articles on their preparations. Sad to say, there are plenty of physicians who will do this; some among them make an actual business of it, as they offer their services as scientific propagandist for every new remedy that turns up. It would be highly commendable if the Medical Chambers would turn their attention to this scandal, even if for nothing more than to call the attention of physicians at large to it more than in the past. It may be difficult, however, to find a remedy for it, as it is seldom possible to prove that an author has written for pay. But, on the other hand, much would be gained if the reputable medical press would be more critical of works devoted to the recommendation of new manufactured remedies. The articles of certain authors, well known to all attentive readers of the medical press, which appear again and again with recommendations of new remedies in the various journals, should be rejected by the editors of first-class medical publications and should not be mentioned in the abstracts of the current literature department. If the medical press becomes closed to such articles, the manufacturing chemists will have no further use for them and they will not care to pay for them."

The time is ripe to have this great evil taken up in the United States.

Commercial Journalism.

The following is a copy of a letter to a firm which advertises a proprietary remedy from a monthly medical journal that is presumed to be published in the interests of physicians:

"*Gentlemen:*—We intend to establish a new department in our magazine. Its purpose will be to teach the successful application of drugs and other remedial agents. Our contributors will be invited to make use of this new department and we expect it to become of considerable interest and value to our subscribers. The name of this department will be 'Modern Therapeutics.' It will be conducted on a liberal and broad-gauge plan. It will follow our original department.

"Its value to the general practitioner will lie in its up-todateness and liberalism. The usefulness of an ethical pharmacal product with an established reputation could be dwelt on in this department with much propriety. The value and range of usefulness of ———— might be discussed in these columns with considerable interest to our subscribers and benefit to you. *We could secure a high-grade original paper dealing with the indications for your preparation and its merit as a therapeutic agent. This paper would embrace about 1,000 words, would be prepared by a good writer and trained clinician and would be based on actual clinical knowledge of your product.* We would have experimental work done along lines that would enable us to secure first-hand knowledge of your preparation's value.

"In view of the preparation and publication of the paper we propose, we feel sure you would be willing to place a page advertisement in our columns. But aside from this the ———— ———— has sufficient merit to warrant your advertising patronage. The ———— is one of the best known medical magazines in the country and as an advertising medium takes rank with the best. It has been published for — years and has a circulation of 10,000 copies among the best men in all parts of the country. We shall allow you a discount of 35 per cent. from the attached card of rates.

"We should like to learn your views on this proposition, all the more so since it is somewhat out of the ordinary and has, we believe, considerable merit. Thanking you for your reply, we beg to remain, Yours very truly,

"———— ————."

A Good Answer.

Cincinnati, Sept. 11, 1905.

Dear Doctor:—If you have a case of Bright's disease or diabetes that is giving you trouble, we desire to call your atention to two new diuretics prepared by the John J. Fulton Company, of San Francisco.

They come to us so highly recommended that we thought it our duty to place them in the hands of the profession of this city and vicinity.

They are free from narcotics or sedatives and are purely eliminative.

Exhaustive tests show that 87 per cent. of cases of chronic nephritis begin within twenty days (sometimes earlier) to show gradual subsidence of the albumin and casts and increasing specific gravity.

The modification of the diuretic used in diabetes mellitus seems equally effective, the results soon showing decrease in the specific gravity, sugar and thirst.

Should this interest you, call for a pamphlet, or we can mail you one giving reports of scientifically conducted tests in a large variety of cases. Yours respectfully,

A. Fennel & Son, Sole Agents.

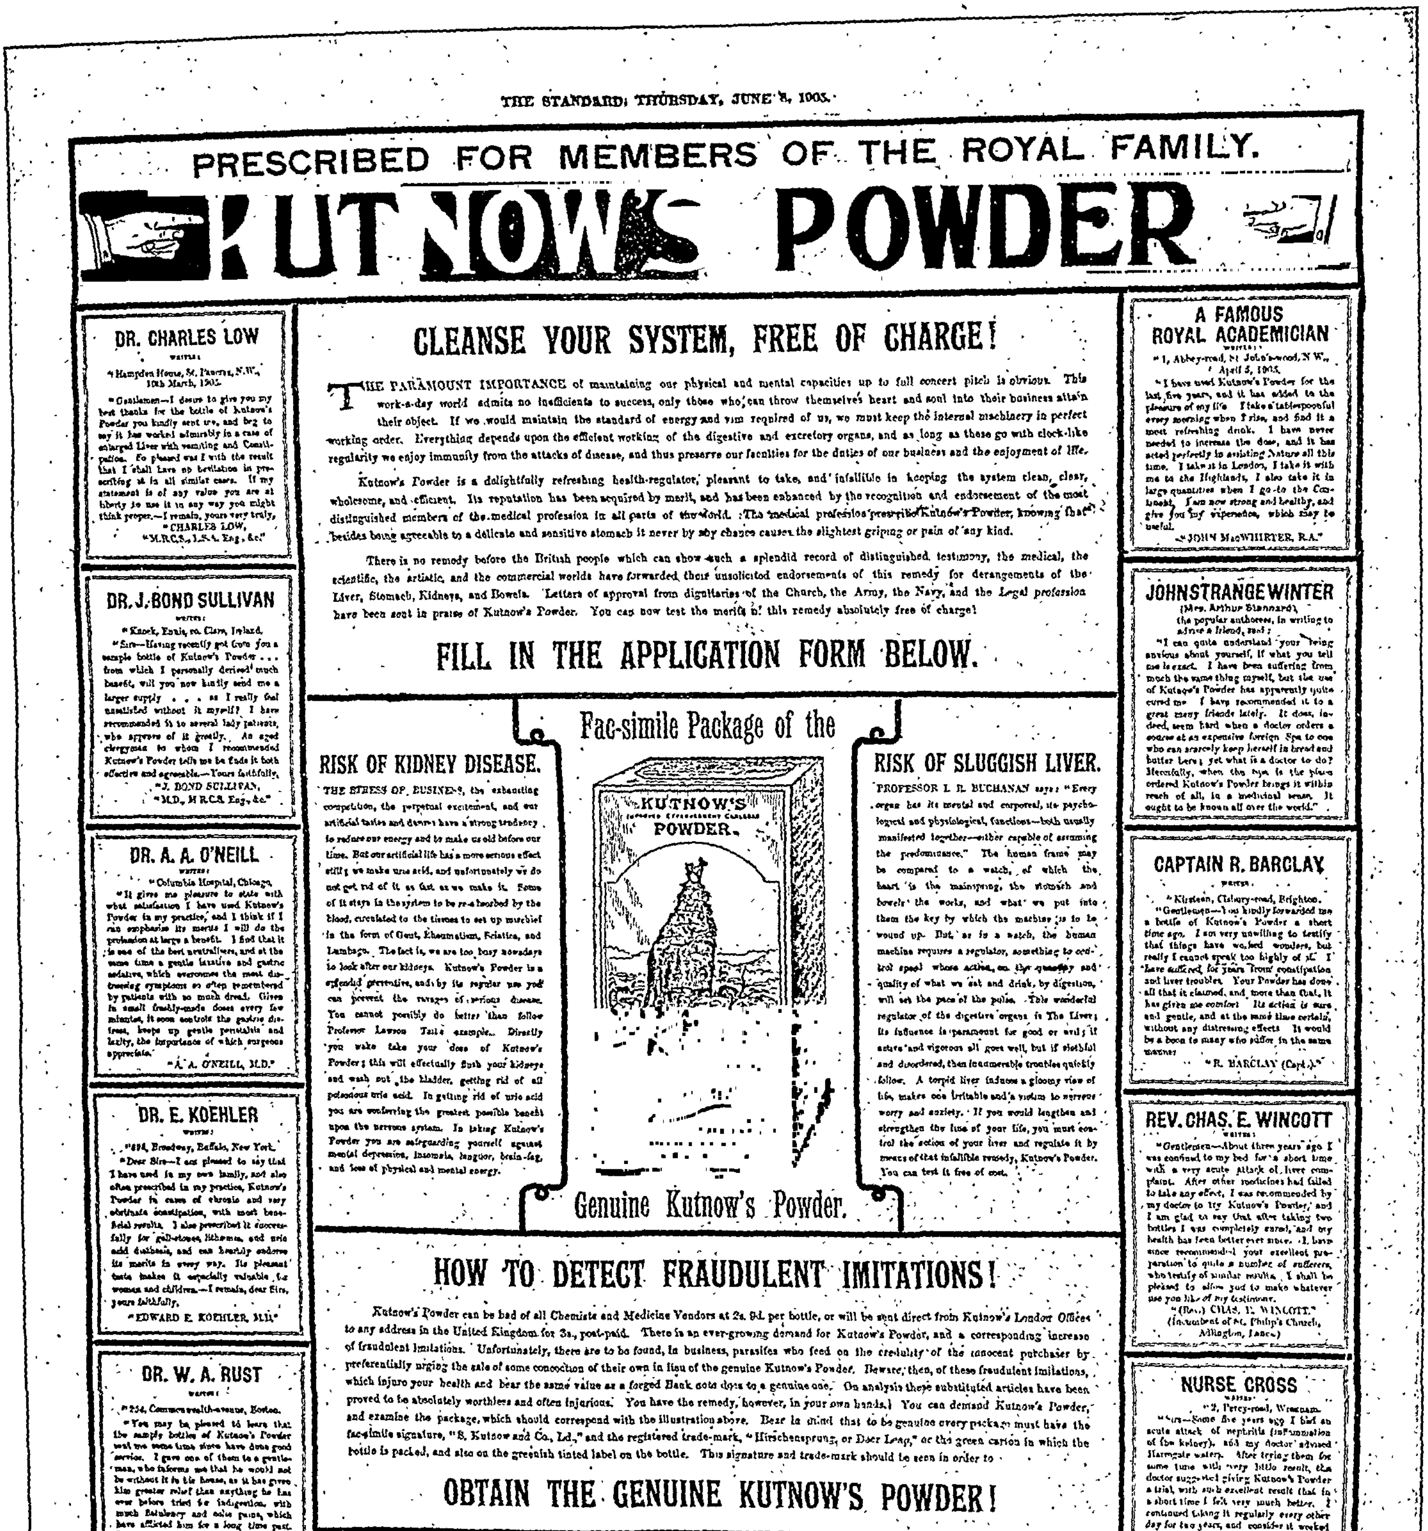
Sept. 19, 1905.

My Dear Mr. A. Fennel & Son, Druggists:—When we want any advice from you on how to cure *Bright's disease*, or *diabetes mellitus*, we will let you know. Geo. B. Orr.

P. S.—I might add that I am getting tired of this thing of having the *patent medicine men* telling members of the *regular profession* how to practice medicine.—*Cincinnati Lancet-Clinic*, Sept. 23, 1905.

---

Koehler is a graduate of the Niagara University, Buffalo, 1894. Dr. William R. Jones is professor of chemistry and toxicology in University Medical College, Richmond, Va., *and graduated from the University of Virginia in 1892.*



THE STANDARD: THURSDAY, JUNE 8, 1905.

PRESCRIBED FOR MEMBERS OF THE ROYAL FAMILY.

KUTNOW'S POWDER

DR. CHARLES LOW

WRITES:

"Hampden House, St. Pancras, N.W.,
10th March, 1905.

"Gentlemen—I desire to give you my best thanks for the bottle of Kutnow's Powder you kindly sent me, and beg to say it has worked admirably in a case of enlarged Liver with vomiting and Constipation. So pleased was I with the result that I shall have no hesitation in prescribing it in all similar cases. If my statement is of any value you are at liberty to use it in any way you might think proper.—I remain, yours very truly,

"CHARLES LOW,
"M.R.C.S., L.S.A. Eng., &c."

DR. J. BOND SULLIVAN

WRITES:

"Knock, Ennis, co. Clare, Ireland.

"Sirs—Having recently got from you a sample bottle of Kutnow's Powder . . . from which I personally derived much benefit, will you now kindly send me a larger supply . . . as I really feel unsatisfied without it myself? I have recommended it to several lady patients, who approve of it greatly. An aged clergyman to whom I recommended Kutnow's Powder tells me he finds it both effective and agreeable.—Yours faithfully,

"J. BOND SULLIVAN,
"M.D., M.R.C.S. Eng., &c."

DR. A. A. O'NEILL

WRITES:

"Columbia Hospital, Chicago.

"It gives me pleasure to state with what satisfaction I have used Kutnow's Powder in my practice, and I think if I can emphasise its merits I will do the profession at large a benefit. I find that it is one of the best neutralisers, and at the same time a gentle laxative and gastric sedative, which overcomes the most distressing symptoms so often remembered by patients with so much dread. Given in small freshly-made doses every few minutes, it soon controls the gastric distress, keeps up gentle peristalsis and laxity, the importance of which surgeons appreciate.

"A. A. O'NEILL, M.D."

DR. E. KOEHLER

WRITES:

"894, Broadway, Buffalo, New York.

"Dear Sirs—I am pleased to say that I have used in my own family, and also often prescribed in my practice, Kutnow's Powder in cases of chronic and very obstinate constipation, with most beneficial results. I also prescribed it successfully for gall-stones, lithæmia, and uric acid diathesis, and can heartily endorse its merits in every way. Its pleasant taste makes it especially valuable for women and children.—I remain, dear Sirs, yours faithfully,

"EDWARD E. KOEHLER, M.D."

DR. W. A. RUST

WRITES:

"254, Commonwealth-avenue, Boston.

"You may be pleased to learn that the sample bottles of Kutnow's Powder sent me some time since have done good service. I gave one of them to a gentleman, who informs me that he would not be without it in the house, as it has given him greater relief than anything he has ever before tried for indigestion, with much flatulency and colic pains, which have afflicted him for a long time past. I am fully satisfied that your preparation is superior to anything of the kind with which I am acquainted.

"WM. A. RUST, M.D."

PROF. W. R. JONES, M.D.,

WRITES:

"I am constantly prescribing Kutnow's Powder, with invariably good results. I also use it myself in order to regulate the functions of the digestive and excretory organs. It is especially beneficial in stimulating a sluggish liver, preventing biliousness and dyspepsia, and permanently removing the baneful effects of chronic constipation."

"W. R. JONES, M.D."
(Professor of Medical Chemistry and Toxicology, University College, Tennessee.)

CLEANSE YOUR SYSTEM, FREE OF CHARGE!

THE PARAMOUNT IMPORTANCE of maintaining our physical and mental capacities up to full concert pitch is obvious. This work-a-day world admits no inefficients to success, only those who can throw themselves heart and soul into their business attain their object. If we would maintain the standard of energy and vim required of us, we must keep the internal machinery in perfect working order. Everything depends upon the efficient working of the digestive and excretory organs, and as long as these go with clock-like regularity we enjoy immunity from the attacks of disease, and thus preserve our faculties for the duties of our business and the *enjoyment of life.*

Kutnow's Powder is a delightfully refreshing health-regulator, pleasant to take, and infallible in keeping the system clean, clear, wholesome, and efficient. Its reputation has been acquired by merit, and has been enhanced by the recognition and endorsement of the most distinguished members of the medical profession in all parts of the world. The medical profession prescribe Kutnow's Powder, knowing that besides being agreeable to a delicate and sensitive stomach it never by any chance causes the slightest *griping or pain of any kind.*

There is no remedy before the British people which can show such a splendid record of distinguished testimony, the *medical,* the scientific, the artistic, and the commercial worlds have *forwarded* their unsolicited endorsements of this remedy for derangements of the Liver, Stomach, Kidneys, and Bowels. Letters of approval from dignitaries of the Church, the Army, the Navy, and the *Legal profession* have been sent in praise of Kutnow's Powder. You can now test the merits of this remedy absolutely free of charge!

FILL IN THE APPLICATION FORM BELOW.

RISK OF KIDNEY DISEASE.

THE STRESS OF BUSINESS, the exhausting competition, the perpetual excitement, and our artificial tastes and desires have a strong tendency *to reduce our energy and to make us old before our time.* But our artificial life has a more serious effect still; we make uric acid, and unfortunately we do not get rid of it as fast as we make it. Some of it stays in the system to be *re-absorbed* by the blood, circulated to the tissues to set up mischief in the form of Gout, Rheumatism, Sciatica, and Lumbago. The fact is, we are too busy nowadays to look after our kidneys. Kutnow's Powder is a splendid preventive, and by its regular use you can prevent the ravages of serious disease. You cannot possibly do better than follow Professor Lawson Tait's example. Directly you wake take your dose of Kutnow's Powder; this will effectually flush your kidneys and wash out the bladder, getting rid of all poisonous uric acid. In getting rid of uric acid you are conferring the greatest possible benefit upon the nervous system. In taking Kutnow's Powder you are safeguarding yourself against mental depression, insomnia, languor, brain-fag, and loss of physical and mental energy.

Fac-simile Package of the

Genuine Kutnow's Powder.

RISK OF SLUGGISH LIVER.

PROFESSOR L. R. BUCHANAN says: "Every organ has its mental and corporeal, its psychological and physiological, functions—both usually *manifested together—either capable of assuming* the predominance." The human frame may be compared to a watch, of which the heart is the mainspring, the stomach and bowels the works, and what we put into them the key by which the machine is to be wound up. But, as in a watch, the human machine requires a regulator, something to control speed whose action, on the quantity and quality of what we eat and drink, by digestion, will set the pace of the pulse. This wonderful regulator of the digestive organs is The Liver; its influence is paramount for good or evil; if active and vigorous all goes well, but if slothful and disordered, then innumerable troubles quickly follow. A torpid liver induces a gloomy view of life, makes one irritable and a victim to nervous worry and anxiety. If you would lengthen and strengthen the line of your life, you must control the action of your liver and regulate it by means of that infallible remedy, Kutnow's Powder. You can test it free of cost.

HOW TO DETECT FRAUDULENT IMITATIONS!

Kutnow's Powder can be had of all Chemists and Medicine Vendors at 2s. 9d. per bottle, or will be sent direct from Kutnow's *London Offices* to any address in the United Kingdom for 3s., post-paid. There is an ever-growing demand for Kutnow's Powder, and a corresponding increase of fraudulent imitations. Unfortunately, there are to be found, in business, parasites who feed on the *credulity* of the *innocent* purchaser by preferentially urging the sale of some concoction of their own in lieu of the genuine Kutnow's Powder. Beware, then, of these fraudulent imitations, which injure your health and bear the same value as a *forged* Bank note does to a genuine one. On analysis these substituted articles have been proved to be absolutely worthless and often injurious. You have the remedy, however, in *your own* hands. You can demand Kutnow's Powder, and examine the package, which should correspond with the illustration above. Bear in mind that to be genuine every package must have the fac-simile signature, "S. Kutnow and Co., Ld.," and the registered trade-mark, "Hirschensprung, or *Deer Leap,*" on the green carton in which the bottle is packed, and also on the greenish tinted label on the bottle. This signature and trade-mark should be seen in order to

A FAMOUS ROYAL ACADEMICIAN

WRITES:

"1, Abbey-road, St. John's-wood, N.W.,
April 5, 1905.

"I have used Kutnow's Powder for the last five years, and it has added to the pleasure of my life. I take a tablespoonful every morning when I rise, and find it a most refreshing drink. I have never needed to increase the dose, and it has acted *perfectly* in assisting Nature all this time. I take it in London, I take it with me to the Highlands, I also take it in large quantities when I go to the Continent. *I am now strong and healthy,* and give you my experience, which may be useful.

"JOHN MacWHIRTER, R.A."

JOHN STRANGE WINTER

(Mrs. Arthur Stannard),

the popular authoress, in writing to advise a friend, said:

"I can quite understand your being anxious about yourself, if what you tell me is exact. I have been suffering from much the same thing myself, but the use of Kutnow's Powder has apparently quite cured me. I have recommended it to a great many friends lately. It does, indeed, seem hard when a doctor orders a course at an expensive foreign Spa to one who can scarcely keep herself in bread and butter here; yet what is a doctor to do? Mercifully, when the Spa is the place ordered Kutnow's Powder brings it within reach of all, in a medicinal sense. It ought to be known all over the world."

CAPTAIN R. BARCLAY

WRITES:

"Kirsteen, Clabury-road, Brighton.

"Gentlemen—You kindly forwarded me a bottle of Kutnow's Powder a short time ago. I am very unwilling to testify that things have worked wonders, but really I cannot speak too highly of it. I have suffered for years from constipation and liver troubles. Your Powder has done all that it claimed, and more than that. It has given me comfort. Its action is sure and gentle, and at the same time certain, without any distressing effects. It would be a boon to many who suffer in the same manner.

"R. BARCLAY (Capt.)."

REV. CHAS. E. WINCOTT

WRITES:

"Gentlemen—About three years ago I was confined to my bed for a short time with a very acute attack of liver complaint. After other medicines had failed to take any effect, I was recommended by my doctor to try Kutnow's Powder, and I am glad to say that after taking two bottles I was completely cured, and my health has been better ever since. I have since recommended your excellent preparation to quite a number of sufferers, who testify of similar results. I shall be pleased to allow you to make whatever use you like of my testimony.

"(Rev.) CHAS. E. WINCOTT."
(Incumbent of St. Philip's Church, Adlington, Lancs.)

NURSE CROSS

WRITES:

"2, Percy-road, Wrexham.

"Sirs—Some five years ago I had an acute attack of nephritis (inflammation of the kidney), and my doctor advised Harrogate waters. After trying them for some time with very little result, the doctor suggested giving Kutnow's Powder a trial, with such excellent result that in a short time I felt very much better. I continued taking it regularly *every other day for two years,* and consider it worked an entire cure. Many of my patients have tried it with excellent results. I think the *wonderful* good done in such cases should be widely known for the benefit of other sufferers.

"MARGARET CROSS (Nurse)."

MR. LOUIS BECKE,

the Australian Novelist,

writing to Messrs. Kutnow and Co. from the Continent for a supply of Kutnow's Powder for a friend suffering from liver complaint, says: "I regard your preparation as an invaluable one, especially in cases of congested liver and malarial fever. From my own experience I may mention that I honestly believe that Kutnow's Powder saved my life last year in the West Indies, where I was suffering at sea from both complaints, and medical attendance was not obtainable."

Photograph of a page of the (London) *Standard*. The original size of the advertisement is 18 by 24 inches. It is a specimen of the advertising of Kutnow's powder in England.

Queries and Minor Notes

INSTITUTIONS FOR STAMMERERS.

Dr. H. C. J. inquires for institutions for the training of stammerers.

MEDICAL DEFENSE COMPANIES.

Chicago, Ill., Oct. 16, 1905.

To the Editor:—Kindly inform me whether you consider the companies insuring practitioners of medicine against suits for alleged malpractice reliable. Also, give me names of some which you can recommend. H. D. W.

Answer.—There are many companies insuring to physicians defense malpractice suits, and it is becoming very common with physicians—and surgeons especially—to be insured in such companies. There are two advertising in The Journal, both of which we consider reliable, viz., The Physician's Defense Co., Fort Wayne, Ind., and The Fidelity and Casualty Co., New York, N. Y. The former is strictly a physician's defense company, the latter conducts a physician's defense department in connection with other insurance business.

LIFE INSURANCE POLICIES AND THE RECENT EXPOSURES OF DISHONESTY.

Mulberry Grove, Ill., Oct. 16, 1905.

To the Editor:—In view of recent exposures regarding the old line insurance companies what do you think of the endowment policy as an investment for physicians? I have two policies in the New York Life, one for $2,500, on which four premiums have been paid, and one for $1,000, on which three premiums have been paid. Would you advise me to continue the policies? I think this question of vital importance to physicians, and a statement from The Journal would evidently prove of interest.
E. A. Glasgow.

Answer.—It is generally understood by those who ought to know that there is nothing whatever in the recent life insurance exposures that show the least indication that the companies will be unable to meet their contracts. It is agreed that the assets, reserves and guarantee funds are intact. To surrender a policy, therefore, and to start over again at the higher rate of a later age would be unwise. The relative value of endowment policy, life policy, or other forms of insurance contract is a matter of the personal needs and tastes of the individual. With a large family of dependents and relatively small income, the discriminating buyer of insurance chooses a life policy because securing the most protection for the least annual expenditure. The endowment is excellent for the man with no dependents or with dependents provided for or who wishes a personal return in old age from his insurance.

State Boards of Registration

COMING EXAMINATIONS.

State Board of Health of Kentucky, Louisville, October 24, Secretary, J. N. McCormack, Bowling Green.

Nebraska State Board of Health, State House, Lincoln, November 8-9. Secretary, George H. Brash, Beatrice.

Board of Registration of Medicine, in Maine City Building, Portland, November 14. Secretary Wm. J. Maybury, Saco.

Connecticut Medical Examining Board, City Hall, New Haven, November 14-15. Secretary, Charles A. Tuttle, New Haven.

Board of Registration in Medicine of Massachusetts, State House, Boston, November 14-15. Secretary, E. B. Harvey, Boston.

State Board of Health of West Virginia, Clarksburg, November 14-16. Secretary, H. A. Barbee, Pt. Pleasant.

Massachusetts September Report.—Dr. E. B. Harvey, secretary of the Board of Registration in Medicine of Massachusetts, reports the written and oral examination held at Boston, Sept. 12-13, 1905. The number of subjects examined in was 9; total number of questions asked, 60; percentage required to pass, 70. The total number of candidates examined was 95, of whom 65 passed, including 7 non-graduates, and 30 failed. Representatives of the following colleges passed:

The Public Service

Army Changes.

Changes of stations and duties of medical officers, U. S. Army, week ending October 14, 1905.

Devereux, John R., asst.-surgeon, granted leave of absence for 20 days, about October 1.

Carter, Edward C., surgeon, leave of absence extended ten days.

McCaw, Walter D., surgeon, detailed to represent the Medical Department of the Army at International Sanitary Convention of American Republics, Washington, Oct. 9, 1905.

Edie, Guy L., surgeon, returned to duty, attending surgeon's office, Washington, D. C., Oct. 2, from duty with the Secretary of War in the Philippine Islands.

Reilly, John J., asst.-surgeon, leave of absence granted for six months on surgeon's certificate of disability.

Wilson, Compton, asst.-surgeon, leave of absence extended fourteen days.

Crabtree, George H., asst.-surgeon, relieved from present duties and ordered to duty with Isthmian Canal Commission.

Bispham, William N., asst.-surgeon, granted leave of absence for three months, about November 1.

Munson, Edward L., asst.-surgeon, ordered to Washington, D. C., for examination for promotion.

Ebert, Rudolph G., surgeon, Raymond, Thos. U., surgeon, relieved from present duties in time to sail from San Francisco, Cal., Jan. 5, 1906, for duty in the Philippines Division.

Roberts, William, asst.-surgeon, order for duty in the Philippines Division revoked.

Hathaway, Levy M., asst.-surg., ordered to Fort Thomas, Ky., for duty.

McCaw, Walter D., surgeon, appointed member of board to investigate various systems of personal identification now in use.

Crampton, Louis W., deputy surgeon general, ordered from St. Louis Mo., to Grand Haven, Mich., and return, on medical supply business.

Vaughan, Milton, contract surgeon, left Fort Crook, Neb., for his home, Little Rock, Ark., for annulment of contract.

Kelly, John P., contract surgeon, relieved from duty at Fort Riley, Kans., and ordered to Presidio of Monterey, Cal., for duty.

Shellenberger, James E., contract surgeon, ordered to Fort Brown, Tex., for temporary duty.

Koyle, Fred. T., contract surgeon, ordered to Fort Ringgold, Tex., for temporary duty.

Thorp, Charles W., contract surgeon, left Plattsburg Barracks, N. Y., for proper station, Fort Ethan Allen, Vt.

Lauderdale, Clarence E., dental surgeon, returned to Fort Sam Houston, Tex., from leave of absence.

White, J. Samuel, contract surgeon, returned to Fort Snelling, Minn., from duty with troops on practice march.

Kennedy, James S., contract surgeon, granted leave of absence for one month.

Sievers, Robert E., contract surgeon, returned from Fort Yellowstone, Wyo., to his proper station, Fort Harrison, Mont.

Wing, Franklin F., dental surgeon, ordered from Fort Riley, Kansas, to Fort Des Moines, Ia., for one month, and then to Jefferson Barracks, Mo.

Waddell, Ralph W., dental surgeon, ordered from Fort D. A. Russell, Wyo., to Fort Mackenzie, Wyo., for ten days and then to Fort Crook, Neb.

Dade, Waller H., contract surgeon, left Fort Duchesne, Utah, on ten days' hunting leave.

Koyle, Fred T., contract surgeon, returned to duty at Fort Bliss, Texas, from leave of absence.

White, J., Samuel, contract surgeon, granted leave of absence for two months.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending October 11:

Geddings, H. D., asst. surgeon-general, re-detailed for duty in the Bureau, effective September 25.

Bailhache, P. H., surgeon, granted leave of absence for six days from October 8, under paragraph 189 of the regulations.

Magruder, G. M., surgeon, granted extension of leave of absence for one month from September 26, on account of sickness.

Young, G. B., P. A. surgeon, granted leave of absence for two days.

McMullen, John, P. A. surgeon, to proceed from Gulfport to Jackson, Miss., and report to P. A. Surgeon G. B. Young for special temporary duty.

Berry, T. D., P. A. surgeon, relieved from duty at Gulfport, Miss., and directed to proceed to New Orleans, and report to Surgeon J. H. White for special temporary duty.

Glover, M. W., P. A. surgeon, relieved from duty at Victoria, B. C., and directed to proceed to Vancouver, B. C., for duty.

Stimson, A. M., asst.-surgeon, granted leave of absence for seven days from October 4, under paragraph 191 of the regulations.

Rodman, J. C., acting asst.-surgeon, granted leave of absence for seven days from October 12.

Scott, E. B., pharmacist, granted leave of absence for five days from October 4, under paragraph 210 of the regulations.

Ryder, L. W., pharmacist, granted leave of absence for seven days from October 16.

RESIGNATION.

W. H. Keen, pharmacist, resigned to take effect October 5.

Medical Organization

MEDICAL ORGANIZATION IN MINNESOTA.

By J. N. McCormack, M.D.

Chairman of the Committee on Organization of the American Medical Association.

BOWLING GREEN, KY.

The two weeks' itinerary planned for me in Minnesota by Dr. McDavitt, the efficient and popular secretary of the Minnesota State Medical Association, enabled me to meet representative physicians of every district and of almost every county, to hear their opinions of the plans for and possibilities of a real organization of the profession by means of a universal system of live county societies, and to discuss with them the professional conditions and needs of each locality, and furnished a most interesting and instructive field for study while on the ground, and much food for reflection since.

Two meetings were called for St. Paul, one especially for the profession of that city and one a week later for the joint benefit of it and of the seventh councilor district. Neither was well attended, and I got the impression in these meetings and from other sources that a singular apathy has fallen on the profession there, for a long time considered one of the strongest and most virile in the Northwest. The meetings at Minneapolis, Duluth, St. Cloud, Fergus Falls, Wodena, Mankato, Redwood Falls and Rochester were all well attended and representative, and were fully alive to the problems involved in this reform movement when the plans for bringing it all about and the benefits which it would bring to both the profession and public were explained to them. In fact, I have been in no section where there was greater avidity to learn the latest and most practical plans for improvement in scientific, legislative and business work or more intelligent enthusiasm manifested in putting them into operation. Along with these impressions I got that of high personal and professional standards, especially in the younger men, and in the newer sections of the state. The fees, too, were more than double those of many of the eastern and middle states, and the schedules were adhered to more uniformly.

As Minnesota is not yet an organized state in the modern sense, having only begun its real work a little more than two years ago, and having now but two-fifths of the eligible physicians in the membership, a study of the influences which had operated to produce these favorable conditions had many fascinations for me, especially in the light of my observations in other states and sections. An inquiry into their medical history soon convinced me that they were traceable primarily to intelligent and, at the outset at least, well enforced legislation regulating the practice of medicine, secured in 1887, mainly through the personal efforts of Drs. Perry H. Millard, Franklin Staples and James B. McGaughey. As a result of such legislation this was one of the first states to require a three years' graded course of study, and the standards were soon put so high that students from Minnesota attended only the best medical schools, and it naturally came about that few outsiders presented themselves for examination who did not come from similar institutions. This gave a high caste to the profession, and the state, being a new one, with little overcrowding, with the bulk of the profession made up of young and middle-aged men who had been subjected to high tests of qualification, and with the better compensation which was evident on every hand, it was easy to understand why the lack of organization for a long time did not result so disastrously as in the older states, or even in the newer ones in which the laws were less perfect or had been so administered as to have less elevating and protective value.

As an evidence of the correctness of these estimates of causes and effects, in recent years, coincident with the phenomenal increase of wealth and population, and especially of the urban development, vigilance in the enforcement of the law relaxed, with the result that quackery in every form and variety on the outside, and commercialism in the shape of contract practice and commissions on the inside, have made rapid and dangerous inroads on the profession. As if to emphasize the futility of high standards on the statute books for permanent protection without such an organization as will support and enforce them, the quack interests, finding the profession without the power of practical co-operation, have been able to dictate legislation to such an extent as greatly to strengthen their own hands and to discourage the friends and supporters of scientific medicine. The physicians were disposed to blame everybody but themselves for their defeats, but the history of it was but a repetition of the old story of the routing of the well-meaning, divided and tactless hosts of a great profession by the small but compact, well-disciplined and unscrupulous forces of quackery. With such an organization in every county as would make possible a union of all of the forces which should be at the constant command of the profession for the proper protection of its own and the public interests, including the State Board of Medical Examiners, the State Board of Health and the medical schools, under well selected and tactful leadership, all necessary legislation ought to be obtained within the next few years. To my mind it is especially important here, and in other states where it has not already been done, to have incorporated in the medical law a provision for the examination of the adherents of new or unusual systems of healing, now in existence or which may hereafter be discovered, that they may be taken care of without special legislation, and before they gain a sympathetic and noisy following. With this should go a plain, strong and practical revoking clause for dishonest professional claims and conduct, criminal abortions and addiction to the liquor or drug habit, which should be operated mainly in an educational and preventive way after ridding the state of the present crop of advertising charlatans. It is easy to see, however, that each year of delay in getting together and securing such legislation will greatly increase both the difficulties and the dangers.

As might have been expected, with such a personnel as I have described making up the bulk of its profession, Minnesota was one of the first states to attempt reorganization under the new plan. Through haste and misapprehension this attempt was abortive, the council and house of delegates features being left out entirely and a year lost. When this mistake was corrected, as a temporary and doubtful expedient, district societies, covering large areas and meeting at long intervals, were substituted for county societies over most of the state. Dr. Fullerton, chairman of the council, took the field actively, and although handicapped with such an imperfect system, greatly increased both the membership and interest and laid the foundation on which the complete organization can be built. I urged that county societies be formed within these districts in every county containing as many as four or five physicians, retaining the district organizations for a comparison of methods of work in the county societies composing them at an annual meeting held midway between the meetings of the state society. I am more and more convinced every day that a [illegible] of the profession in this country is only po[illegible] agency of county societies, and that the [illegible] and the benefits greater and more easily obtained in small than in large counties. If doctors can only rid themselves of the delusion that numbers, noise, long papers and sonorous discussions are essential for a successful medical society, and that they are organized and exist for the purpose of bringing them together so frequently and in such a way that their differences will naturally harmonize themselves, and after that, for scientific improvement and for working out the various and important business and legislative problems so important to them, it will be easy to organize the profession in almost an ideal way.

No state which I have visited is more susceptible of such a complete organization than Minnesota, but nearly everything remains to be done. Unfortunately, few of the councilors have realized the importance and responsibilities of their positions as organizers and peacemakers, and have attempted to perform the little work they have undertaken by correspondence. The state society has generously proposed to pay them for their time and for all expenses incurred, and each of them should visit every county in his district by appointment once or twice before the next annual meeting, notifying all physicians of the time and place by personal letters, and securing the active co-operation of the leaders of the profession in each county in working up the meeting. It is only by such close personal work that effective organization can be accomplished, but it will be worth all that it costs many times over, and if the medical colleges will heed the request of the Portland session of the House of Delegates and give their future classes a practical course of instructions along business, ethical, legislative and other co-operative lines, it will never have to be done over again and the reform will be permanent. At the close of several of the meetings committees were appointed to formulate plans for the postgraduate courses and for carrying out other features of the practical work suggested by me. At Rochester, under the leadership of Dr. Mayo, arrangements were promptly made for such a scientific course in their society. With the facilities they have for carrying it on, a postgraduate course can be made of inestimable value to the local members, and, what is even far more important, it can and will be so conducted as to make it such an object lesson to the numerous visitors to that great medical center as will carry its benefits in time to every section of the country.

The work in Minnesota was very laborious and exacting on account of the widely separated meeting places, but it was relieved and made pleasant by the evident appreciation of the altruistic purposes of the American Medical Association in sending me to assist them and by a hospitality and cordiality which was as constant as it was delightful. I go next to North Dakota, and then on to Montana, Washington, Idaho, Oregon, California, Texas and Oklahoma, filling appointments which have already been made for me by the associations of those states, meeting and discussing local conditions and methods for improving, with the profession of some city, district or county almost every day, and reaching home in time for the Christmas holidays.

California.

Solano County Medical Society.—This society effected permanent organization on the standard plan at Vallejo August 31. Dr. H. O. Miller, Vallejo, presided, and Dr. Philip Mills Jones, San Francisco, secretary of the Medical Society of the State of California, addressed the meeting on the benefits of organization and detailed the plans and work of the state society and the affiliated county societies.

North Dakota.

Cass County Medical Society.—A number of the members of the Cass County Medical Society and physicians of Moorhead, Minn., met at Fargo September 19, when Dr. J. N. McCormack, Bowling Green, Ky., delivered an address on "Organization."

Ohio.

Huron County Medical Society.—With the aid of Dr. William E. Lower, Cleveland, councilor for the fifth district, this society was organized at Norwalk September 5. Dr. Thomas C. Martin, Cleveland, spoke on "The Advantages of Organization," and Dr. Clyde E. Ford of Cleveland on the "State Medical Journal." Dr. Daniel W. Loney, Norwalk, was elected president; Dr. Morton W. Bland, Bellevue, vice-president, and Dr. John A. Sipher, Norwalk, secretary and treasurer.

(Concluded from page 1190.)

Further Experiments with Vaccine Virus.

Dr. W. F. Elgin, Glenolden, Pa., said that winter vaccine may be expected to remain active for 125 days. This period shortens as the weather gets warmer. A temperature of about 70 degrees hastens the destruction of virus, so that summer vaccine can only be expected to remain active for a short time.

Glycerinate virus immediately placed in cold storage not only remains active for a long period, but when removed after a storage of several months will stand practically the same conditions as to change of temperature as that noted in control virus removed from the animal at the time the stored virus is taken from cold storage. This will allow of the preparation of vaccine during the cold weather, and its storage for summer distribution; so that vaccine plants may close down during the extreme heat.

The virus contained in capillary tubes remains active practically as long as the same virus in bulk, while a slight deterioration is noted in the glycerinated vaccine on points.

The life of vaccine taken from the deeper skin layers, or that part of the vesicle remaining after the normal or usual vaccine tissue has been removed, is very nearly if not quite the same as that of the normal virus; while the bacteria are decidedly fewer in number and more restricted in character.

No sure method has been universally accepted which will secure both purity and potency in virus prepared for general distribution. Many laboratories, particularly those under state control in this country and abroad, have practically given up bacteriologic control as a routine procedure. It is a question how far we are justified in clearing vaccine of bacteria at the expense of its potency.

Danger of Tuberculosis Dissemination by Railway Travel Is Exaggerated.

Dr. Charles P. Dudley, Altoona, Pa., stated that during the past few years the railroads have been called sharply to account for remissness in sanitary matters. He discussed the extent to which this criticism is justified, for example, as to the spread of tuberculosis. It is obvious that if the spread of tuberculosis is largely due to contact of the healthy with those who are affected, the railroads, under present conditions, can hardly be held responble, since there is no means by which ticket agents or conductors can be sure as to diagnosis, and to refuse transportation on an erroneous diagnosis would lead to serious trouble. If, on the other hand, the spread of tuberculosis is largely due to pulverized, dried sputum, the railroads may fairly be regarded as responsible, and may be required to take greater precautions. Careful studies seem to indicate that the dangers of infection from dried sputum on care have been greatly magnified. As items pointing in this direction may be mentioned: First, the length of time of passengers on cars is small at the longest, while prolonged exposure seems to be agreed on as a marked characteristic in the acquisition of this disease; second, tuberculous sputum is extremely difficult to dry; third, even though artificially dried it is extremely difficult to pulverize; fourth, though artificially dried and pulverized, it is heavy, and does not readily remain suspended in the air; and, fifth, cars from their construction, afford very great advantages to the access of sunlight and air, which are more or less fatal to this form of disease germ. Furthermore, if cars are such a menace as has been supposed, it would seem that employes of the sleeping-car companies and of the railroad companies, whose occupation requires that they spend much time on the cars, would be largely affected. The statistics gathered at the last census, as reported by Dr. George M. Sternberg in his book, "Infection and Immunity," show that railroad men are less affected by tuberculosis than the average of persons of the whole country. Furthermore, information from the Pullman Company does not show that the colored porters who are supposed to be predisposed to tuberculosis, and who spend a large portion of their lives on sleeping cars, are more affected than others. The records of the Pennsylvania Railroad, in connection with its relief department, show that passenger conductors and brakemen are not as frequently affected with tuberculosis as are the freight conductors and brakemen. Again, bacteriologic examinations of the air from cars known to have transported tuberculous patients, the results of which have been recently published by Dr. J. J. Kinyoun, do not indicate any alarming prevalence of tubercle bacilli in these cars. Finally, experiments made for the purpose, as to the behavior of tuberculous sputum on carpets and plush, show that analogous material is less likely to become dry and to be pulverized and disseminated in the air, than if this material is on a hard, non-absorbent surface.

Car Sanitation.

Dr. Henry M. Bracken, Minneapolis, said that to advance car sanitation it is not only necessary to improve the methods of car construction, but to instruct railway employes in the proper care of cars. Special duties should be imposed on them as to ventilation, car cleanliness, etc. Their instructors should be medical men connected with railway companies and familiar with sanitary problems. He pointed out the dangers from spitting on the floors or furnishings of cars. He discussed car cleaning, and said more attention should be given to this subject. The drinking water for railway cars should be of unquestionable quality, distilled or equally pure, and should be kept out of reach of passengers, except as drawn from the faucet, should be stored in well-cleaned cans or coils, and iced with well-selected ice that has been handled in a cleanly manner. He advocated improvement in the toilet rooms of the day coaches.

The Restriction of Contagious Diseases in Cities.

Dr. Charles V. Chapin, Superintendent of Public Health, Providence, R. I., said that modern municipal sanitary practice was first based on the filth thory of disease. During the last twenty-five years it has been largely determined by the recognition of the contagiousness of the infectious diseases. Further practice will be modified by specific knowledge as to the etiology of each disease. The chief sanitary discovery of recent years is that unrecognized foci of infection are the principal factors in the spread of contagious disease. This is bound to modify present methods, rendering them less burdensome. Stringent measures can not stamp out disease. All that can be hoped for is to limit extension from the recognized cases. This can be done substantially as well by moderate means. No restriction of personal liberty is advisable in influenza, pneumonia, typhoid fever or cerebrospinal meningitis. In measles and whooping cough there should be some restriction of school attendance and the occasional closure of school. In scarlet fever and diphtheria the patient should be isolated for three or four weeks and other children in the family kept from school. Wage-earners should rarely be interfered with. The use of cultures to terminate isolation in diphtheria as ordinarily practiced is illogical. Hospital facilities are needed only for the poor. Official disinfection does more harm than good. When the above diseases appear for the first time in small places, or rather when rarer diseases appear in large cities, the most energetic measures are called for.

Modification of Present Port Inspection.

Dr. A. H. Doty, health officer, New York, pointed out the necessity for a change in the present method of quarantine inspection, which will insure a more thorough examination of passengers and crews. There should be closer observation for the detection of mild or ambulant cases. This type is commonly the cause of outbreaks, the origin of which are unknown, and which are frequently improperly attributed to infection by cargoes, clothing, etc. While five days may be regarded as the maximum period of incubation of yellow fever, the fact that a person has been five days away from an infected area should not permit him to pass quarantine without having his temperature taken and the use of other means to detect the presence of mild cases. This should also be applied to the examination of those held to complete the period of incubation of other diseases. Furthermore, the possibility of occasional cases having a longer period of incubation than that generally accepted must be remembered.

Communicability of Cerebrospinal Meningitis and the Means of Controlling Its Spread.

Drs. William H. Park and Charles Bolduan, New York City, stated that out of fifteen hundred cases in New York City, two hundred were in direct contact with other cases, and many showed evidence of infection from other cases. These two hundred represented eighty-eight families. Bacteriologic examinations revealed that about half the cases of meningitis had abundant meningococci in the nasal cavity during the first two weeks of the disease, and that the nasal cavities of five attendants were badly infected. The conclusion is drawn that the meningococci are spread by the discharges from the nose and mouth of the sick and those in immediate contact with them.

Method of Securing More Uniform Instruction and Co-operation in Health Work.

There was a symposium on this subject. Prof. F. C. Robinson, Brunswick, Maine, and Prof. W. T. Sedgwick, Boston, discussed educational co-operation with the general public in public health work. Prof. H. C. Ernst, Boston and Dr. J. D. Adami, Montreal, spoke of graduate and under-graduate instruction in hygiene in universities and medical colleges. Mr. W. D. Frost, Madison, discussed the teaching of hygiene in the public schools. Dr. S. H. Durgin, Boston, pointed out the present regulations and laws as to the qualifications and methods of appointment of executive and technical health officers, while Dr. H. D. Pease, Albany, emphasized the importance of sanitary conferences and schools of instruction for health officers.

The Collection and Preservation of Samples of Sewage for Analysis.

Mr. Stephen D. Gage and Mr. George O. Adams, Massachusetts, stated that in collecting samples of sewage and the effluents of sewage filters for analysis, more representative samples would be obtained if each sample is the average of a number of small samples taken at short intervals. The preservative used must prevent chemical changes. Two preservatives which best fulfill these conditions are chloroform and carbon bisulphid. Both destroy the bacteria and prevent all bacteriolytic decomposition; both are sparingly soluble in water, and being heavier than water they do not evaporate rapidly, requiring small amounts to be used in each sample. Both are comparatively inexpensive, and neither interferes with any of the usual analytical methods.

Dr. Hamilton Wright, beri-beri research commissioner of the London School of Tropical Medicine, read a paper on beri-beri.

Methods of Bacteriologic Examination of Milk.

Dr. Francis H. Slack, Boston, described the apparatus and methods in use at the Boston Board of Health Laboratory for collecting, plating, incubating and counting; also for direct examination of milk sediments and the microscopic estimate of the number of bacteria present, together with pus and streptococci determination. The methods of examination described are recommended as a system which has been reasonably successful in practice for city laboratory work, where quick reports are needed, as well as the accurate examination of large numbers of samples.

Problems and Difficulties of Bacteriologic Diagnosis.

Mr. Bert R. Rickards, Boston, discussed some of the every-day problems and difficulties met with in making bacteriologic diagnoses. Each disease discussed was considered, first, in relation to any special points connected with the preparation of the specimen submitted; second, in regard to those problems which have to do with accuracy in diagnosis; and, third, with reference to results and their relation to the clinical aspect of the case.

Longevity of Bacillus Typhosus in Surface Waters and Sewage.

Prof. H. L. Russell and Mr. C. A. Fuller, Madison, Wis., reported that from their experimental work it appears that in relatively pure water of a surface character the typhoid bacillus is capable of retaining its vitality for about eight days. The results of their experiments confirm and extend on a broader basis the data obtained in the investigations made on the Chicago Drainage Canal. They have been carried out under sufficiently diverse conditions to warrant the belief that the typhoid organism in natural sewage does not live as long as it will in relatively pure water.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Thirty-first Annual Meeting, held at Indianapolis, Oct. 10-12, 1905.

The President, Dr. Bransford Lewis, St. Louis, in the Chair.

Addresses of welcome were delivered by Mayor John W. Holtzmann on behalf of Indianapolis, and by Dr. W. N. Wishard on behalf of the local profession, which were responded to by Dr. H. O. Walker, Detroit.

The scientific work was divided into two sections, medical and surgical.

Nostrum Exposures Commended.

The following preamble and resolution were unanimously adopted by the surgical section:

Whereas, The medical profession keenly realizes the great and increasing public evil, moral, mental and physical, arising out of the support given by the public press to the so-called patent medicine interests, leading to the pernicious practices of self-drugging, narcotic habituation, and alcoholic excess; be it

Resolved, That the Mississippi Valley Medical Association commends and frankly endorses the attitude adopted by *Collier's Weekly* and the *Ladies' Home Journal* in giving publicity in the articles by Samuel Hopkins Adams, Norman Hapgood, and Edward Bok, respectively, to the truthful exposure of the nefarious practices and unscrupulous methods of the so-called patent medicine concerns.

Officers.

The following preamble and resolution were unanimously *President*. Dr. J. Henry Carstens, Detroit; vice-presidents, Dr. Joseph Rilus Eastman, Indianapolis, and H. H. Gr

Louisville, Ky.; secretary, Dr. Henry Enos Tuley, Louisville, Ky. (re-elected); treasurer, Dr. S. C. Stanton, Chicago (re-elected).

Hot Springs, Ark., was selected as the place for holding the *next annual meeting.*

Surgical Dressing.

Dr. Carl E. Black, Jacksonville, Ill., presented a preliminary report on the technic of the after-dressing of surgical cases. He pointed out briefly the principal elements necessary for the proper dressing of a wound, whether it be a surgical or an accidental wound. While the technic differs somewhat in different kinds of tumors, the fundamental principles are the same in all. Certain modifications must always be made to suit the individual case. Septic wounds should be so dressed that there is no opportunity for a further mixture of infection in the wound, nor any opportunity for the infectious material from the wound to in any way be scattered where it can come in contact with other wounds. These two points should always be kept prominently in mind by those undertaking the dressing of wounds.

DISCUSSION.

Dr. O. H. Elbrecht, St. Louis, said that the use of a standard size of dressings, tapes, etc., would lessen confusion on the part of the surgeon in going from one hospital to another to operate.

Dr. Miles F. Porter, Fort Wayne, Ind., said that the keynote of success in the management of surgical cases is system and simplicity. One should attempt to do away with the necessity of dressing wounds until they have healed in all cases where this is possible. There should be no stitches to remove in the ordinary aseptic wound, no matter where it is located, and in the ordinary treatment of septic cases the rule, as it prevails, makes necessary a great deal more subsequent dressing than is called for. The redressing of a wound should be looked on as an evil to be avoided, if possible.

Curettage in Septic Cases.

Dr. C. E. Ruth, Keokuk, Iowa, reported in detail four cases of puerperal sepsis which illustrated the dangers of curettage.

DISCUSSION.

Dr. O. H. Elbrecht thinks that many deaths are due to the curette being used in cases of septic uteri. It is just as criminal, in his opinion, to introduce a curette into a septic or infected uterus as it is a sound or curette for the purpose of producing criminal abortion. He mentioned a case in which a physician curetted a uterus contrary to his advice, and the next day the patient died. He mentioned two other cases of sapremia which terminated fatally from what he believes to be a curettement of the uterus.

Dr. H. O. Walker, Detroit, strongly condemned the indiscriminate use of intrauterine curettes and irrigators. Many deaths are undoubtedly due to their improper use.

Dr. John Young Brown said that the curette has an important function to fulfill. Where there are decomposing membranes or fragments of retained placenta the uterus should be cleaned out.

Dr. Hannah M. Graham, Indianapolis, uses an applicator, around which cotton is wrapped, saturated with carbolic acid, and the débris left in the uterus is swabbed out. It is her practice, too, to use a fenestrated catheter as a drainage tube, through which peroxid of hydrogen is injected every two or three hours, by herself or the nurse, and she has had good success by this method.

Dr. A. M. Hayden, Evansville, Ind., thinks that a physician called to see a patient whose uterus contains a broken-down fetus or fragments of placenta, and who fails to clean out the uterus is criminally negligent. He advocates placental forceps for removing debris without disturbing Nature's protection.

Dr. Thomas B. Noble, Indianapolis, defended the uterine curette. It is an instrument for prevention as well as cure. The proper way is to interpret the pathology that one has to contend with, remembering that the curette is a means to an end. If a woman is suffering from high temperature, rapid pulse, prostration, due to septic material in the uterus, which can be removed by mechanical means, the physician does her an injustice if he leaves her uterus alone, simply trusting to Nature to take care of it.

Dr. G. Frank Lydston, Chicago, said if one is called to see a woman who is suffering from general sapremia, who is in such a condition that it is evident dissolution is not far away if something is not done, if the history is such that material has been left in the uterus, and she is having a temperature of 105 degrees, he would certainly not treat such a woman surgically or provide drainage by way of the vagina, but would remove the septic material from the uterus. If this is not done the case is doomed, and many women in such a condition recover under proper intrauterine treatment.

Dr. Ruth called attention to the failure to differentiate between the varieties of infection that one has to deal with. There is no danger from a careful curettement in a case of putrescent uterus in which a septicemia is not added to the intoxication of sapremia.

Artificial Hyperemia in Surgery.

Dr. Alexander C. Wiener, Chicago, pointed out the indications for the Bier method in surgery, as follows: 1. Subacute mild inflammations of joints and soft tissues are rapidly relieved. 2. Acute purulent inflammations of soft tissues either on the extremities or the head can be relieved by this method. 3. Acute and subacute inflammation of joints and purulent arthritis; gonorrheal infections of joints, etc. In these cases the elastic bandage has to be applied in such a manner as to produce energetic venous stasis, without causing pain to the sufferer. In acute inflammations comparatively light constriction produces extensive hyperemia. This conclusively shows that the arterial blood is not diminished, but slackened. Cases were cited in which excellent results were obtained by the Bier method.

Surgery of the Gallbladder and Its Ducts.

Dr. H. O. Walker, Detroit, related his experience with 185 cases on which he has operated. He quoted from a former paper written by him several years ago, adding that what he said then still obtains to-day. First, jaundice, which heretofore has been regarded as almost pathognomonic of the presence of gallstones, is present in only about 20 per cent. of all stone cases. Second, that pain in the region of the gall bladder does not by any means indicate the presence of gallstones, but is as often the result of a kinking of the cystic duct from lesions the result of one or more attacks of cholecystitis combined with pericholecystitis. Third, the passage of stones in the feces is not as common as was formerly supposed, for colics are rarely successful in passing a stone from the gall bladder. Fourth, empyema of the gall bladder is not always determined by palpation, for frequent attacks of cholecystitis tend to diminish the size of the gall-bladder. Fifth, tumors of the gall bladder without pain or jaundice indicate a simple dropsy, while a painful, distended gall bladder indicates empyema, and when accompanied by jaundice indicates constriction of the choledochus. Sixth, a hard, nodular, painful tumor of the gall bladder, with or without jaundice, is almost certain evidence of carcinoma. Seventh, obstruction of the choledochus, accompanied with inflammation and jaundice, quickly disappears after the passage of the stones into the papilla of the duodenum.

Cholelithiasis is of greater frequency than is supposed. Approximately every tenth individual has concretions in the gall bladder, yet only about one in twenty ever complains of their presence, so that quiet stones need no treatment. It is only the cholecystitis and cholangitis which make manifest the irritable presence of gallstones without demanding treatment, both medicinal and surgical.

The conditions that require operative intervention are: 1. An acute sero-purulent cholecystitis, and accompanying pericholecystitis. 2. Persistent and frequent pains due to adhesions between the gall bladder, intestines, stomach and omentum. 3. Chronic obstruction of the common duct. 4. Chronic empyema of the gall bladder and its accompanying accidents.

Cholecystectomy is undoubtedly advisable where the gall bladder has been subject to frequent attacks of inflammation, and where chronic septic conditions exist.

(To be continued.)

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Annual Meeting, held in Scranton, Sept. 26-28, 1905.
(Continued from page 1189.)

Acquired Hydrocephalus with Atrophic Bone Changes, Exophthalmus and Polyuria.

Dr. Thomas W. Kay, Scranton, exhibited a boy of 7 years who three years ago had scarlatina. Three years later there was vertigo and enlargement of the superior cervical and submaxillary gland, with subsequent loss of the teeth and softening of the bones of the head. Exophthalmos appeared eighteen months ago, and at present the eyes are too prominent for the use of glasses and have to be protected by a handkerchief. The lower jaw has lost its bone salts and the chin has disappeared. As much as 27 ounces of urine are passed at a time.

Adaptation of the Public to the Prevention of Tuberculosis.

Dr. Howard S. Anders, Philadelphia, said that there is greatly needed a general adaptation, especially by officialdom, representative bodies, landlordism and various big corporations, to the doctrine that no conditions are socially or morally permissible which foster the propagation of tuberculosis. Adaptation also calls for the avoidance of the extremist, the alarmist, and the irrational antagonist, and between these, the fatalist. The sanatorium movement was emphasized as the most far-reaching and efficient means of attacking the tuberculosis menace. Much, he said, might be accomplished for the public health were the street dirt removed at night and the dust during the day kept down by sprinkling. He advocated the installment of a cabinet officer at Washington at the head of a department of public health.

Diagnosis of Incipient Pulmonary Tuberculosis.

Dr. George W. Norris, Philadelphia, said that the diagnosis could not be based on any one symptom or physical sign, but must be made in the light of the whole complex. Careful consideration of the anamnesis is of the greatest importance. Before beginning the examination of the chest the patient should be instructed to breathe properly, and enlargement of the bronchial or cervical lymph nodes should always be looked for. Rapid pulse or slight evening rise of temperature, if persistent or inexplicable on other grounds, he regards as suggestive, especially if associated with loss of weight, diminished capacity for work, or cough. With the occurrence of any two of the last named symptoms for a protracted period, the physician should show cause why a diagnosis of tuberculosis should not be given. In the event of uncertainty the patient should be treated as if he had the disease.

Sanatorium Treatment of Tuberculosis.

Dr. George B. Kalb, Erie, made a plea for the early diagnosis of tuberculosis, and urged that dependence be not put on the microscopic examination of sputum. He favored the establishment of three clases of institutions: 1, For incipient cases; 2, for advanced cases; 3, for far advanced cases.

Outdoor Life versus Confinement in the Treatment of Bone Tuberculosis.

Dr. H. Augustus Wilson, Philadelphia, detailed the results obtained at Atlantic City, Coney Island, Wellesley Hills, Blue Ridge Summit, Toronto and elsewhere. He has found that osseous tuberculosis does not demand the varied atmospheric conditions necessary in the treatment of phthisis; that sleeping in tents or shacks with the temperature almost at zero F. has not been injurious; that various operative and corrective measures require consideration in connection with outdoor life; that there has been general improvement in the health and strength, and that no condition has been found too serious for betterment.

Dr. M. P. Ravenel, Philadelphia, thought it the physician's duty to instruct his patients, his clergyman and his legislator in the truths concerning tuberculosis. Unless an early diagnosis is made and the patient becomes a non-bacillary expectorating individual, the disease in a community can never be eradicated. This education he believed as important as a cure. In treatment he would direct attention chiefly to rest, circulation and digestion. In the forced feeding of patients he warned against the danger of unclean milk.

Dr. Charles A. E. Codman, Philadelphia, in giving milk and eggs has the yolks and whites beaten separately and then the whites poured on the yolks, with the addition of sugar, salt or a flavoring.

Dr. Guthrie, Wilkesbarre, believed that local deposits of tuberculosis should, if possible, be subjected to surgical procedure.

Dr. Norris said that in the wards of the Phipps Institute in Philadelphia the routine treatment for hemorrhage is to put the patient to bed, apply an ice-bag to the chest, give a hypodermic injection of morphia, and assure the patient that there is no immediate danger. Ergot is never given.

Dr. Ravenel varies the treatment for hemorrhage with the condition of the patient's blood pressure. He gives nitroglycerin as indicated.

Address in Otology.

Dr. Michael V. Ball, Warren, gave a brief summary of the accomplishments of otology in the last four years.

Present Treatment of Squint.

Dr. William Campbell Posey, Philadelphia, said that all children were more or less predisposed to squint, dependent primarily on vicious optical conditions. The vision in the squinting eye rapidly deteriorates. Treatment was outlined as follows: 1, The improvement of the vision in the defective eye; 2, neutralization of the farsightedness and the lessening of the accommodative effort; and, 3, the strengthening of the nervous and muscular mechanism which controls the movements of the eyes, and the cultivation of the desire for binocular vision. Attempts to improve the vision should be inaugurated promptly, since improvement can not be secured in subjects over 6 years of age. He would prescribe glasses at the early age of 2 or 3 years, and at a later age the vision may be further improved by the use of the amblyoscope, a modified form of stereoscope. In certain cases he was hopeful of improvement only by tenotomy. The amblyoscopic exercises should be continued for a year or more subsequent to operation.

Dr. S. D. Risley, Philadelphia, believes binocular vision to be a matter of experience; for example, an infant will reach out for an object, but its hands will never go directly toward the desired object until by experience it has learned where the object is and how to find it. This he mentioned as a species of muscular sense acquired by experience. In binocular vision, in like manner, the infant has to learn to use both eyes at the same time and converge on the object. He believed that anatomic anomalies account for the fact that one child readily acquires binocular vision while another child secures it only with the aid of optical appliances.

Herpes Zoster Ophthalmicus.

Dr. Edward Stieren, Pittsburg, stated that his observation of six cases of the ophthalmic variety of the disease included two showing a wide disparity in the eruptive process and ocular involvement, and that the two might be considered classical illustrations of the extremes of herpetic eruption following the course of the fifth nerve. One patient suffered an enucleation, while in the other case a bleb observed on the limbus disappeared, leaving a decided scar and a slight patch of congestion which persisted for several months. In all his cases Dr. Stieren has been able to trace a history of exposure to cold or dampness after some unusual exercise with consequent fatigue in individuals of otherwise sedentary habits.

Dr. Zentmayer, Philadelphia, cited a case complicated by the occurrence of ocular motor palsy and corneal ulcer in which the ulcer recovered promptly, but in which the palsy was of several years' duration.

Dr. Stieren thought the disease seemed to run a self-limited course and that there was a certain amount of immunity given a patient who had had the disease. Rather against the hypothesis that the disease is an acute infectious disease was the fact that seldom, if ever, is more than one case found in a household.

The Mastoid Operation.

Dr. Edward B. Dench, New York City, believed that in 90 per cent. of mastoiditis the disease is secondary to an inflammation of the middle ear. The most characteristic symptom,

will remove both the undigested food and the products of fermentation which cause the increased peristalsis. If there be proteid indigestion the process can be checked by resorcin, .39 gm. (6 gr.) four times daily, to which 1.25 c.c. (20 m.) of tincture of nux vomica should be added, if there is diminished motor function of the stomach. After a few days the faulty digestion may be corrected by three drops of strong nitrohydrochloric acid or 10 drops of dilute hydrochloric acid, with 3 mg. (1/20 gr.) of strychnin sulphate, given in the midst of each meal. Pepsin may be serviceable.

As a rule in amylaceous indigestion there is constipation. Occasionally there is diarrhea which, if present, is best corrected by thorough mastication of starchy foods, and limitation of fluids with their ingestion. The author discountenances the use of sodium bicarbonate in all gastric and most intestinal indigestion and recommends the use of magnesia ponderosa in 10 gr. (.65 gm.) doses after meals.

NERVOUS.

When diarrhea is caused by emotion attention must be given to the mental instability. The associated symptoms are often marked and require special attention. Permanent cure can come only from moral suasion accompanied by removal of all sources of mental irritation. Temporarily this symptom is checked by the following prescription:

℞. Ammonii bromidi..................gr. xv | 1
Spiritus ammonii aromat..............ʒi | 4

M. Sig.: Give at one dose.

The neurotic forms due to hysteria, neurasthenia, migraine, and the climacteric, require careful treatment, based on the underlying cause. The best results are obtained from the persistent use of the bromids, preferably strontium bromid (free from barium salts) .4 gm. (60 to 90 gr.) daily. After three days this may be diminished in quantity, and the solution of potassium arsenite commenced. Three drops are given thrice daily, and the dose is increased one drop a day until slight untoward symptoms supervene.

The reflex diarrheas from cold are almost invariably relieved by the daily use of a morning cold bath. The tub bath should commence with the temperature of 88 F., and be taken cooler by a degree or so each morning until 68 F. or even 58 F. is reached. A five-minute bath followed by brisk rubbing with a turkish towel results in a vigorous reaction, and the morning bath soon becomes not only a therapeutic necessity, but a luxury as well. In addition, an abdominal bandage made of flannel should be constantly warm.

HEMIC.

Of the hemic diarrheas the uremic is perhaps the most striking. In this form opium is emphatically contraindicated. The proper method of dealing with this condition is the administration of a high intestinal irrigation with normal saline, in quantity a gallon, of the temperature of from 112 to 116 F., through a rectal tube inserted at least twelve inches; the reservoir should be elevated about three feet. If chronic nephritis is predominating the sodium chlorid should be replaced by sodium bicarbonate. Intestinal irrigation will free the intestine from irritating contents, will enable the kidneys to perform their function more properly, and will also stimulate the heart.

Malarial diarrhea is best treated by arsenic, methylene blue, or the following combination:

℞. Ext. ergotæ.......................gr. ii | 13
Berberin sulph......................gr. i | 06
Piperin ....gr. ss | 03

M. Ft. capsule No. i. Sig.: One such capsule four times a day.

By far the best diet in chronic diarrhea is milk. This should be given between meals and at bedtime and must not be taken cold. For the meals, tea, poached eggs on toast, rare grilled or broiled steak or lamb chops, fresh chopped beef, with 2 c.c. (30 m.) of hydrochloric acid to each 60 gm. (2 oz.) meat soups, with thoroughly boiled rice, toast instead of bread, soft-boiled eggs, with half a bottle of Burgundy of good vintage, will take the patient well toward the time when a regular mixed diet may be resumed. To be avoided are fruits, raw or sour, cooked and sweetened succulent vegetables, foods leaving much residue and sugar.

Of improper methods of treatment may be cited opium. This is only admissible when the alimentary canal has been thoroughly emptied, to check excessive peristalsis. It should be given hypodermatically as morphin, in substantial doses, and not repeated. Astringents, as experience has taught us, when introduced into the alimentary canal, do not astringe; they are even likely to irritate.

Syphilis.

Kilbane, in the *Medical Record*, recommends the hypodermic use of the salicylates of mercury in the treatment of every case of syphilis in which the administration of mercury is indicated for a period of time. The author states that he has given it a very considerable trial, both in dispensary work and in private practice, and claims for it many advantages. He further states that as a rule the patient makes no objection to this method of treatment if its advantages are clearly explained, and complains little of pain after the first two or three treatments. The author recommends the following technic:

The dose to begin with is usually three-fourths of a grain (.04). The interval between treatments is four days. The dose and the length of the intervals between the treatments are gradually increased until the patient is taking one and one-half grains (.09) weekly. The full dose of a 10 per cent. preparation, therefore, is 15 minims. If the patient has been taking mercury in some other manner a larger dose may be used at the start. In some cases a dose larger than a grain and a half may be used to combat special symptoms, but in these cases the more frequent use of a soluble salt of mercury will probably give better results. Potassium iodid can be administered by mouth at the same time.

An ordinary hypodermic syringe does very well. The needle should be at least one and a quarter inches in length and about 18 caliber. Needles of smaller caliber are impracticable because the mercury will clog in them. It is essential that the needle be very sharp. In private practice he has found it advisable to sterilize the needle immediately after use, and to keep needle, syringe and forceps for handling in an alkaline strongly antiseptic solution ready for immediate use when required. The gluteal region is the usual site of injection, alternating from side to side. The muscles of the back or the calf of the leg may be used if desired. The buttock is cleaned, as is usual for hypodermic injection.

The patient's leg is placed so as to relax the gluteal muscles, and he is instructed not to jump when the injection is made. The syringe is filled with mercury, the needle is attached and air bubbles excluded. The needle is entered firmly and quickly into the muscles as far as the guard, care being taken to avoid injuring the periosteum. The relations of the anatomic structures in the vicinity should be borne in mind. The mercury is then driven very gently and slowly into the muscles, the needle quickly withdrawn, and the part massaged with a vigorous rotary motion for one minute. This massage prevents any hemorrhage from the puncture hole and lessens very materially the probability of any soreness or lameness following.

Medicolegal

Free Pasteur Treatment for Needy Persons.—No. 68 of the Laws of Pennsylvania of 1905 provides that in each and every county of the state it shall be the duty of the proper officers of the several poor-districts, in such counties, to provide all needy persons, in their said several districts, who may be bitten by dogs suffering from hydrophobia or rabies, with the proper medical attention to prevent the development of the disease in the person or persons so bitten, which medical attention may include the treatment known as the Pasteur treatment.

To Secure Purer Fruit Syrups.—No. 217 of the Laws of Pennsylvania of 1905 provides that any person, firm or corporate body who shall, by himself, herself or themselves, or by his, her or their agents or servants, manufacture, sell, ship, consign, offer for sale or expose for sale, or have in possession with intent to sell, any fruit syrup which contains formalin his opinion, is tenderness on firm pressure over the mastoid process. He regards the prognosis as excellent. He has had but twenty deaths in 489 operations, and in none was death due to mastoid involvement. He described the operation in detail. The second incision, which extends horizontally backward from the middle of the curvilinear one, has rarely been necessary in his practice. Three possibilities of accident were enumerated: 1, Failure on the part of the operator to find the mastoid antrum; 2, injury to the lateral sinus; 3, injury to the facial nerve. Emphasis was placed on the fact that even in those cases perforating simultaneously through the internal table of the mastoid, operative technic should be the same as in a case which had not perforated the cortex. He allows the cavities to fill up by granulation.

Mastoiditis—Its Importance in General Practice.

Dr. S. MacCuen Smith, Philadelphia, gave a brief outline of the historical aspect of mastoiditis and then directed attention especially to its relation to general practice. A physical sign of the greatest diagnostic importance, he said, was the ominous bulging or drooping of the superior and posterior wall of the external auditory canal. The most urgent measure in the treatment of mastoiditis arising from acute tympanic disease he considers to be the early and free incision of the membrana tympani, especially when complicating infectious disease—that is, opening of the drum head during the stage of hyperemia and before the stage of pus formation has been reached. In the after treatment the canal is dried with a cotton wrapped probe and an impalpable powder is dusted on the walls of the canal.

DISCUSSION.

Dr. Taylor, Wilkesbarre, referred to the infrequent employment of the backward incision by Dr. Dench, his own experience having been contrary to this. He believed it important to enlarge the field of operation for thorough investigation of the mastoid. He was glad that Dr. Smith referred to the pernicious idea held by some that a child would outgrow a "running ear," and the conception that it was dangerous to stop a discharge of the ear.

Dr. Kate W. Baldwin, Philadelphia, said that in all cases of septic conditions of the nose and throat the teeth should be examined, and cited a case of a person aged 38 with an unerupted wisdom tooth which had caused mastoid abscess.

Dr. J. H. McKee, Philadelphia, referring to the importance of examining the ear when cerebral symptoms were suspected, thought it far better to adopt the plan of Dr. Morse in the Boston City Hospital of making the examination of the ear a part of the routine examination of the child. Many obscure cases are cleared up in this manner. He said he had yet to see a case of pneumonia, middle ear disease or of typhoid in a child with middle ear disease in which there was not sufficient adenoid tissue to be considered pathologic. The importance of lumbar puncture in the presence of cerebellar complications of middle ear disease should also be remembered.

A Plea for Early Diagnosis and Immediate Local Treatment in Disease of the Accessory Sinuses of the Nose.

Dr. W. G. B. Harland, Philadelphia, called attention to the important part played by the middle turbinate in preventing free drainage, and cited cases showing how quickly relief followed active local treatment. Neuralgic pains of the face, puffiness of the cheek and mucopurulent discharge should always suggest sinus inflammation; in other cases pain, postnasal discharge, or the subjective perception of odor might be the only symptoms. He advocated rest in bed and hot moist applications, calomel and salts, phenacetin, quinin and atropin in acute conditions. Locally, reduction of turbinates with cocain, 4 per cent., and adrenalin, 1 to 5,000; nasal wash, removal of part or whole of middle turbinate, washing of antrum through inferior meatus or alveolus. The more threatening conditions could be referred to specialists; milder cases are treated with opiates and antineuralgics. All cases should receive active local treatment.

Dr. Pyfer, Norristown, said that the general practitioner did not realize that in every case of cold the sinuses were involved, and that the degree of headache confirmed the amount of sinus involvement. If sinus involvement is suspected, in addition to the internal medication, he would prescribe the use of a spray of adrenalin and cocain followed by an alkaline solution.

Dr. Randall, Philadelphia, spoke against prescribing cocain. He uses it sparingly and prescribes it never. In the antrum cases, the pain being so habitually about the first and second molar, the nasal and sinus involvement is apt to be overlooked.

(To be continued.)

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Toxemia of Pregnancy.

McIlwraith, in the *Canadian Practitioner*, recommends the following treatment for these patients, based on the theory that the condition is due to toxemia and that elimination is the curative treatment.

1. If the patient be conscious, he gives calomel grains 5 at once, washed down with saturated solution of magnesium sulphate, 2 ounces. The patient is then anesthetized and given an injection of sterile normal saline, one pint beneath each breast, and at the same time the nurse gives an enema consisting of:

℞.	Magnes. sulph.	℥i	30
	Glycerini	℥ii	60
	Aquæ	℥iii	90

This is given as high up in the bowel as possible. As the patient comes out of the anesthetic a hypodermic of morphin sulphate grain ½ (.03) is given. Chloral grains 30 (2.) per rectum, and morphin sulphate grain ¼ (.06) hypodermically are given alternately at two-hour intervals, as may be required, for convulsions or threatening symptoms. Not more than three grains of morphin should be given in twenty-four hours.

2. If the patient be unconscious, treatment is the same, except that the medicine can not be given by the mouth. This is as far as the treatment can be systematized, but varying conditions may lead the physician to change the treatment in each case. It has been noted on several occasions that the convulsions ceased and the other symptoms disappeared before the bowels started to move; this, the author thinks, is due to serum, and with it toxin, having been withdrawn from the general circulation into the bowel, and remaining there owing to failure of peristalsis. The glycerin enema usually excites peristalsis.

In addition to morphin and chloral, veratrum viride may prove of value in cases in which the pulse is full and of high tension given in doses of from 5 to 10 minims hypodermically t i d. (Nicholson, in the *British Medical Journal*, recommends thyroid extract to combat the pulse tension.) If all these methods fail delivery must be accomplished. The patient may do well for a few days without food, but water is necessary, and may be given by the bowel if the woman is unconscious. Of the use of chloroform to control convulsions the author states, "if a patient is having a series of convulsions, chloroform may be given to break the series, while elimination measures are being taken, but this should be its sole function. Its prolonged administration is exceedingly dangerous."

Chronic Diarrhea.

Wilcox, in *American Medicine*, outlines the treatment of this condition as follows:

The therapeutics of this disease depends on its cause, since it is actually only a symptom. The author classifies the causes, each one of which is again subdivided into mechanical, nervous and hemic.

MECHANICAL.

The treatment of mechanical diarrheas is based on removing the cause of irritation. The dyspeptic form of mechanical irritation is best treated by a full dose of castor oil, which will remove both the undigested food and the products of fermentation which cause the increased peristalsis. If there be proteid indigestion the process can be checked by resorcin, .39 gm. (6 gr.) four times daily, to which 1.25 c.c. (20 m.) of tincture of nux vomica should be added, if there is diminished motor function of the stomach. After a few days the faulty digestion may be corrected by three drops of strong nitrohydrochloric acid or 10 drops of dilute hydrochloric acid, with 3 mg. (1/20 gr.) of strychnin sulphate, given in the midst of each meal. Pepsin may be serviceable.

As a rule in amylaceous indigestion there is constipation. Occasionally there is diarrhea which, if present, is best corrected by thorough mastication of starchy foods, and limitation of fluids with their ingestion. The author discountenances the use of sodium bicarbonate in all gastric and most intestinal indigestion and recommends the use of magnesia ponderosa in 10 gr. (.65 gm.) doses after meals.

NERVOUS.

When diarrhea is caused by emotion attention must be given to the mental instability. The associated symptoms are often marked and require special attention. Permanent cure can come only from moral suasion accompanied by removal of all sources of mental irritation. Temporarily this symptom is checked by the following prescription:

℞. Ammonii bromidi....................gr. xv 1|
Spiritus ammonii aromat..............ʒi 4|
M. Sig.: Give at one dose.

The neurotic forms due to hysteria, neurasthenia, migraine, and the climacteric, require careful treatment, based on the underlying cause. The best results are obtained from the persistent use of the bromids, preferably strontium bromid (free from barium salts) .4 gm. (60 to 90 gr.) daily. After three days this may be diminished in quantity, and the solution of potassium arsenite commenced. Three drops are given thrice daily, and the dose is increased one drop a day until slight untoward symptoms supervene.

The reflex diarrheas from cold are almost invariably relieved by the daily use of a morning cold bath. The tub bath should commence with the temperature of 88 F., and be taken cooler by a degree or so each morning until 68 F. or even 58 F. is reached. A five-minute bath followed by brisk rubbing with a turkish towel results in a vigorous reaction, and the morning bath soon becomes not only a therapeutic necessity, but a luxury as well. In addition, an abdominal bandage made of flannel should be constantly warm.

HEMIC.

Of the hemic diarrheas the uremic is perhaps the most striking. In this form opium is emphatically contraindicated. The proper method of dealing with this condition is the administration of a high intestinal irrigation with normal saline, in quantity a gallon, of the temperature of from 112 to 116 F., through a rectal tube inserted at least twelve inches; the reservoir should be elevated about three feet. If chronic nephritis is predominating the sodium chlorid should be replaced by sodium bicarbonate. Intestinal irrigation will free the intestine from irritating contents, will enable the kidneys to perform their function more properly, and will also stimulate the heart.

Malarial diarrhea is best treated by arsenic, methylene blue, or the following combination:

℞. Ext. ergotæ........................gr. ii |13
Berberin sulph......................gr. i |06
Piperin ....gr. ss |03
M. Ft. capsule No. i. Sig.: One such capsule four times a day.

By far the best diet in chronic diarrhea is milk. This should be given between meals and at bedtime and must not be taken cold. For the meals, tea, poached eggs on toast, rare grilled or broiled steak or lamb chops, fresh chopped beef, with 2 c.c. (30 m.) of hydrochloric acid to each 60 gm. (2 oz.) meat soups, with thoroughly boiled rice, toast instead of bread, soft-boiled eggs, with half a bottle of Burgundy of good vintage, will take the patient well toward the time when a regular mixed diet may be resumed. To be avoided are fruits, raw or sour, cooked and sweetened succulent vegetables, foods leaving much residue and sugar.

Of improper methods of treatment may be cited opium. This is only admissible when the alimentary canal has been thoroughly emptied, to check excessive peristalsis. It should be given hypodermatically as morphin, in substantial doses, and not repeated. Astringents, as experience has taught us, when introduced into the alimentary canal, do not astringe; they are even likely to irritate.

Syphilis.

Kilbane, in the *Medical Record,* recommends the hypodermic use of the salicylates of mercury in the treatment of every case of syphilis in which the administration of mercury is indicated for a period of time. The author states that he has given it a very considerable trial, both in dispensary work and in private practice, and claims for it many advantages. He further states that as a rule the patient makes no objection to this method of treatment if its advantages are clearly explained, and complains little of pain after the first two or three treatments. The author recommends the following technic:

The dose to begin with is usually three-fourths of a grain (.04). The interval between treatments is four days. The dose and the length of the intervals between the treatments are gradually increased until the patient is taking one and one-half grains (.09) weekly. The full dose of a 10 per cent. preparation, therefore, is 15 minims. If the patient has been taking mercury in some other manner a larger dose may be used at the start. In some cases a dose larger than a grain and a half may be used to combat special symptoms, but in these cases the more frequent use of a soluble salt of mercury will probably give better results. Potassium iodid can be administered by mouth at the same time.

An ordinary hypodermic syringe does very well. The needle should be at least one and a quarter inches in length and about 18 caliber. Needles of smaller caliber are impracticable because the mercury will clog in them. It is essential that the needle be very sharp. In private practice he has found it advisable to sterilize the needle immediately after use, and to keep needle, syringe and forceps for handling in an alkaline strongly antiseptic solution ready for immediate use when required. The gluteal region is the usual site of injection, alternating from side to side. The muscles of the back or the calf of the leg may be used if desired. The buttock is cleaned, as is usual for hypodermic injection.

The patient's leg is placed so as to relax the gluteal muscles, and he is instructed not to jump when the injection is made. The syringe is filled with mercury, the needle is attached and air bubbles excluded. The needle is entered firmly and quickly into the muscles as far as the guard, care being taken to avoid injuring the periosteum. The relations of the anatomic structures in the vicinity should be borne in mind. The mercury is then driven very gently and slowly into the muscles, the needle quickly withdrawn, and the part massaged with a vigorous rotary motion for one minute. This massage prevents any hemorrhage from the puncture hole and lessens very materially the probability of any soreness or lameness following.

Medicolegal

Free Pasteur Treatment for Needy Persons.—No. 68 of the Laws of Pennsylvania of 1905 provides that in each and every county of the state it shall be the duty of the proper officers of the several poor-districts, in such counties, to provide all needy persons, in their said several districts, who may be bitten by dogs suffering from hydrophobia or rabies, with the proper medical attention to prevent the development of the disease in the person or persons so bitten, which medical attention may include the treatment known as the Pasteur treatment.

To Secure Purer Fruit Syrups.—No. 217 of the Laws of Pennsylvania of 1905 provides that any person, firm or corporate body who shall, by himself, herself or themselves, or by his, her or their agents or servants, manufacture, sell, ship, consign, offer for sale or expose for sale, or have in possession with intent to sell, any fruit syrup which contains formaldehyd, sulphurous acid or sulphites, boric acid or borates, salicylic acid or salicylates, saccharin, dulcin, glucin, beta-naphthol, abrastol, asaprol, fluorids, fluborates, fluosilicates or other fluorin compounds; also any coal-tar dyes, sulphate of copper, or any other coloring matter injurious to health, or any preservatives or their compounds injurious to health, shall be deemed guilty of a misdemeanor, etc.

To Have State Hospital for the Criminal Insane.—No. 247 of the Laws of Pennsylvania of 1905 provides for a commission of six persons to select a site and build an institution for the treatment and care of the criminal insane of the state. The tract of land selected shall be suitable for the purpose of the hospital, the land to be good arable land, well adapted to the preservation of the health, the occupation and maintenance of the inmates of the hospital, with an adequate supply of good water, and large facilities for drainage from the hospital buildings. The buildings shall be of the best design for the construction of such institution, and without expensive architectural adornment or unduly large or costly administrative accommodations. The board of trustees shall appoint a competent and skillful physician, of special training and experience in the treatment and care of the insane, who shall be superintendent, and shall have charge, supervision and direction of the hospital, both professionally and otherwise, his salary to be fixed by the board of trustees. Whenever the hospital shall have sufficient accommodations for the proper care of a larger number of insane patients than have been committed to it, the committee on lunacy of the state board of charities shall have authority to transfer to it from any other state hospital for the insane, giving the preference in all cases to those patients having known criminal tendencies.

Rules and Regulations to Be Made by Health Departments.—No. 165 of the Laws of Pennsylvania of 1905 provides that all departments of health of the cities of the first class of that commonwealth shall have full power, and shall make, immediately after this act shall become a law, such rules and regulations, which, in their judgment, may be proper and necessary, for the protection of the public health, and amend or alter the same, from the diseases known as cholera, yellow, malarial, typhoid, typhus, scarlet, puerperal and relapsing fevers, smallpox (variola or varioloid), chicken-pox (varicella), diphtheria and membraneous croups, cerebrospinal meningitis, measles, mumps, whooping-cough, tuberculosis (in any of its diverse forms), pneumonia, erysipelas, plague (bubonic), trachoma, leprosy, tetanus, glanders, hydrophobia (rabies) and anthrax. That said rules and regulations shall cover and include: (*a*) The reports to be made by physicians or other persons, in attendance on any person afflicted with any of the said diseases, to said health authorities. (*b*) The quarantining and disinfecting of persons and premises, and the placarding of notices. (*c*) The treatment or disposal of infected bedding, clothing or other articles. (*d*) The care and burial of the bodies of persons who may have died from any of the said diseases, fixing the limit of time for burial, the methods to be used, the attendance of persons, and the style of advertising the funeral. (*e*) The disinfection of conveyances used in the burial of persons who may have died from said diseases, or which may have been used by a person afflicted with any of said diseases, or person who may have been in contact with the same. (*f*) The admission and attendance of persons at public or private schools, hospitals and asylums, or any other public or private educational or charitable institutions, and the compulsory vaccination and revaccination of inmates thereof, and of persons attending the same, or employed therein as physicians, teachers, nurses, or in any other capacity. All rules and regulations and all changes and amendments, when adopted, shall be printed and distributed for public use; copies of the same shall be filed with the state board of health. Copies shall be prepared and furnished to every educational institution, public or private, and to every physician and undertaker, within the jurisdiction of the health authorities promulgating the same.

Health Provisions in Labor Law.—No. 226 of the Laws of Pennsylvania of 1905 provides, among other things, that no child under 14 years of age shall be employed in any establishment. No minor under 16, and no female, shall be employed in any establishment for a longer period than sixty hours in any one week, nor for a longer period than twelve hours in any one day. Every person, firm or corporation employing girls or adult women, in any establishment, shall provide suitable seats for their use, and shall permit such use when the employes are not necessarily engaged in active duties. Every person, firm or corporation employing males and females in the same establishment, shall provide for such employes suitable and proper wash and dressing-rooms, and water-closets for males and females; and the water-closets, wash and dressing-rooms used by females shall not adjoin those used by males, but shall be built entirely away from them, and shall be properly screened and ventilated; and all water-closets shall at all times be kept in a clean and sanitary condition. Exhaust fans of sufficient power, or other sufficient devices, shall be provided for the purpose of carrying off poisonous fumes and gases, and dust from emery-wheels, grindstones and other machinery creating dust. The owner, agent, lessee or other person having charge or managerial control of any establishment shall provide or cause to be provided not less than 250 cubic feet of air space for each and every person in every work-room in said establishment, where persons are employed, and shall provide that all work-rooms, hall and stairways in said establishment be kept in a clean and sanitary condition and properly lighted. No person, firm or corporation engaged in the manufacture or sale of clothing or other wearing apparel, cigars or cigarettes, shall contract for the manufacture of same where to be made in any kitchen, living room or bed room in any tenement or dwelling-house, except where the persons contracting to make any of said articles are members of the family residing in such house, and shall have furnished a certificate from the board of health of the city or town that the house is free from any infectious or contagious disease. All persons, firms and corporations engaged in the manufacture or baking of bread, cakes, crackers, pastry, pretzels or macaroni, for public sale, shall keep their room or rooms for baking, mixing, storing or sale of flour or other grain products separate and apart from any sleeping room, water-closet, urinal, defective drain or sewer pipe, and shall not permit the harboring of any domestic animal therein. The floors of all baking, mixing, storing and salesrooms shall be kept clean and tightly joined and free from crevices, and the walls and ceilings shall be painted, kalsomined or whitewashed as often as twice in each year, and oftener if, in the opinion of the chief factory inspector or his deputy, the safety of the employes or the public shall require.

7 *The State and Federal Public Health Services. J. S. Fulton, Baltimore.

1. **New Type of Parasite in Pernicious Malaria.**—Smith reports the finding in the blood of 119 cases of malaria of a parasite so peculiar and distinct from any previously described as to render it probable that this form is a distinct type of the parasite of pernicious malaria. The parasites are small hyaline discs of an oval spindle form, non-pigmented and lying in the protoplasm of the red blood corpuscles. They have a very sharply defined outline, are highly refractive, and in the center

of each form is a small round dot of hemoglobin. Their short diameters vary from 1/5 to 1/10 the diameter of the red blood corpuscle, their long diameters being about twice as great. On account of their spindle shape, he designates them "spindle forms." They have no ameboid motion, but move by revolving on their long axis and by swinging around on their short axis, using one end as a fixed point. This motion is the most peculiar characteristic of the parasite. They stain with great difficulty and then only the periphery to a slight extent. No development of any nature has been observed in these parasites, and no forms besides these "spindle forms" were ever discovered in the blood before death or in the blood and organs after death in the four fatal cases.

3. **Phlebosclerosis.**—Martin and Meakins find that this condition exists commonly quite apart from diseased arteries and that it is extremely common in peripheral veins, especially those of the lower extremities. Their findings and conclusions may be epitomized thus: (1) Peripheral sclerosis is very common, existing in nearly 60 per cent. of patients examined by them in hospital. (2) It is much more common in young people than is generally supposed, especially in the saphena veins. (3) It is frequently present without any arteriosclerosis. (4) Sections show no signs of marked inflammation or degeneration. Proliferation and hypertrophy of intima and media are the chief pathologic pictures. (5) The usual causes of arteriosclerosis are absent. (6) The condition is allied to a process of functional hyperplasia rather than to chronic inflammation and is not associated, as a rule, with injury, though with prolonged strain from movement, posture and changed blood tension.

6. **After-treatment of Pulmonary Tuberculosis.**—Wilder emphasizes the great tendency toward relapse and chronicity of tuberculous ulceration in the lungs as well as in other parts, e. g., the skin and bones, and thinks there is a tendency at the present time to take too optimistic a view of its curability. The disease is practically always more or less advanced from the pathologic standpoint before it is recognized clinically. Although some patients have such good resistance that they recover in spite of unfavorable surroundings and methods of living, the majority require a continuous life for years rather than months under the most favorable hygienic and meteorologic conditions before there is assurance that their lesions are permanently healed. Placing the patient under proper conditions for a short time often causes the disease to become quiescent, but this is only the first step in the cure of a disease that, on account of the nature and severity of the pathologic lesions, is essentially of long duration. In an analysis of 100 cases of pulmonary tuberculosis that have been at least quiescent for from one to ten years, the average period of quiescence being three years nine months, he finds that at the present time 87 are either quiescent or cured and able to work. Twenty-five of the 100 cases have at some time relapsed. Thirteen of these patients have relapsed and recovered, eight have relapsed and died, and four are at present chronic invalids. One patient died from cancer of the stomach without relapse of his pulmonary trouble. Of these cases 67 were originally classified as incipient and 33 as moderately advanced or advanced. The period of quiescence before working or returning home varies from no time to 36 months, the average being eight months.

7. **State and Federal Public Health Services.**—Fulton discusses the probable influence on state boards of health of the federal law under which the U. S. Public Health and Marine-Hospital Service is now organized. This law, he thinks, will serve the purpose which medical men have long had in mind in advancing a national board of health. Powers and privileges not heretofore accorded to other departments of state government are by this act of Congress conferred on state boards of health. Each year the surgeon-general must call a conference of state boards of health, and he must call an extraordinary conference whenever any five state boards of health unite in a request to the U. S. Public Health Service. The most serviceable feature of the new law is the annual conference, as the orderly and steady progress, which may be made from year to year by concerted efforts, is vastly better than the reforms brought about by the drastic methods of the extraordinary or emergency conference. By co-operation with the federal bureau it is possible to bring a majority of state boards up to good standards of efficiency and to advance the standards steadily. Hitherto there have been no standards. It is the real function of the annual conference to wipe out the spectacle of confusion and discord, of high and constant efficiency in one state, alternating worth and worthlessness in another state, and unvarying inefficiency in a third state. The tendency to exempt boards of health from political spoliation is growing stronger in this country. The people begin to learn that the hygienist is a highly specialized man of science. Boards of health are less commonly regarded as useful only in times of emergency. They have found their routine, and their daily tasks interest the public. The people themselves are now active in some of the problems of special hygiene, and the official hygienist must prove his professional fitness in the company of enthusiastic amateurs. The people demand the suppression of tuberculosis, and the enthusiasm of the voluntary associations now engaged in the American movement against tuberculosis is alarming, because it brings the hygienist into intimate relations with the sociologists, who have a body of useful knowledge about the disease and certain new ideas about its prophylaxis. These new allies will certainly discover our poverty in recorded data, in which they are strong, and can not fail to note the delinquency of boards of health. Strengthened by such co-operation, the forward movement of American hygiene is definitely assured. The kind and degree of success desired may not be fully attained, but the awakening of the people to the possibilities of preventive medicine means, in official life at least, the crack of doom for amateur sanitarians.

8 *Choice of Method in Operating on the Hypertrophied Prostate. W. Meyer, New York.
9 Importance of Differentiation in the Use of Electric Modalities. A. D. Rockwell, New York.
10 *Anatomy and Associated Pathologic Conditions of the Rectum and Colon, with Mechanical Methods of Treatment. F. B. Turck, Chicago.
11 *Case of Combined Extrauterine and Intrauterine Pregnancy. H. T. Miller, Springfield, Ohio.
12 *Asthenopia Due to Latent Hyperphoria. G. De. W. Hallet, New York.

8. **Choice of Operation for Hypertrophied Prostate.**—Meyer advocates the use of the three methods in general use, perineal and suprapubic prostatectomy and galvano-caustic prostatectomy, according as each method fits the case to be treated. Meyer has performed Bottini's operation on fifty-nine patients, perineal prostatectomy nine times, and the suprapubic operation twenty-two times. The only deaths by the perineal method were from the anesthetic in one case, and in a patient almost moribund at the time of operation. Of the twenty-two suprapubic operations, seventeen patients with benign hypertrophy are living, two died of causes not due to the operation; three with cancerous hypertrophy died of causes due to the nature of the disease. Meyer believes that it is possible to cut the grooves with the galvanocautery both deep and wide; that a median lobe is a contraindication to the Bottini operation, if it is possible to do an enucleation; the cystoscope is of value in explaining the conditions at the neck; Bottini's operation, even when done twice, does not prevent a prostatectomy, should that become necessary; but, being a purely intravesical operation, it has many failures, and sometimes entails tedious after-treatment. If radical operation is refused it should be done. There is little choice between the perineal and suprapubic routes. In the perineal operation there is a rapid return to normal control of the urine, and leakage over the abdomen is not present. The suprapubic operation can be done in less time. Cystoscopy should always be performed before Bottini's operation, as the hypertrophy may be entirely intravesical. In advanced carcinoma Bottini's operation is to be preferred, since all the cancerous metastases can not be removed. A gland palpable by rectum and rising not far from the sphincter muscle can best be attacked from below; when higher up and projecting into the bladder it should be operated on from above. When soft and composed of small lobes, it should be operated on from below; when complicated by a large calculus, from above. The preservation of sexual power is important, and the suprapubic method retains it in the largest number of cases.

10. Treatment of Atony of Rectum and Colon.—Turck advises the use of massage and stimulation of the atonic intestine by the use of small rubber bags inserted in the rectum and sigmoid flexure and inflated with air. The inflation can be used steadily for the desired amount of time, or the bag may be alternately relaxed and inflated again, thus producing a kind of massage of the intestine. The abdominal circulation is also an important factor in atony of the intestine, and massage by inflation stimulates the circulation. Drugs, surgery, general gymnastics, and the various mechanical methods of treatment have all failed in curing atony. The injection of air confined in the rubber bag places the amount of distension to be used under the operator's control. It may be made intermittent. Hemorrhoids, ulcers, proctitis, all are benefited, as well as prolapse of the bowel, and various associated uterine conditions.

11. Combined Extrauterine and Intrauterine Pregnancy.—Miller's patient, aged 40, one year ago developed symptoms which indicated an extrauterine pregnancy. On opening the abdomen a cyst-like tumor having a pedicle containing the right Fallopian tube was removed. The cavity of the sac was distended with dark-colored blood and contained the remnants of a placenta and degenerated fetus. The size of the uterus gave rise to the suspicion of an intrauterine pregnancy, which was verified on the second day after the operation by the spontaneous expulsion of a perfectly formed four months' fetus. The patient made an uneventful recovery.

12. *Asthenopia* Due to Latent Hyperphoria.—Hallett describes a case of severe and agonizing neuralgic headache which was permanently relieved after correction of prisms by the existing hyperphoria. The headache, which had persisted for fifteen years, refused to yield to all other treatment, and at times was severe enough to confine the patient to a dark room for several days.

17 Spinal Hemorrhage, Some of Its General Phases. W. Browning, Brooklyn, N. Y.
18 *Vesical Fistula.* H. H. Purinton, Lewiston, Maine.

13. Late Hereditary Syphilis.—Campbell discusses the question whether or not hereditary syphilis can manifest itself for the first time some years after birth by the presence of such late lesions as occur in the acquired form, and with the total absence of the triad symptoms, Hutchinson's teeth, interstitial keratitis and a particular form of deafness known as labyrinthine or central deafness.

14. Spirochaeta of Syphilis.—Fanoni examined material obtained from five cases of primary and secondary syphilis, including chancers, condylomata papules and mucous patches, and found the spirochete of syphilis in all.

15. Sanatorium Provision with Industrial Opportunities.—King and Neagle show that every attempt to organize even moderately large numbers of phthisical patients into self-supporting communities has been uniformly unsuccessful. As the result of personal experience and inquiries made, they conclude that a sanatorium should be on a sound financial basis, independent of its earning capacity, before entering industrial fields. It can not safely rely on financial returns from its industrial features, since the latter are fully as apt to increase as to decrease the expense of administration. If industrial features are introduced, as wide a range of occupations as possible should be at command in order to meet individual requirements in both sexes, and suitable provisions should be made for permitting very light work and short hours to start with in all cases. No patient should be permitted to do work of any kind until sufficient time has relapsed after his admission to establish his physical ability. Medical supervision should be unremitting throughout the patient's sanatorium residence, and allowance in time limit of residence should be made for the relapses which inevitably occur whenever any great number of consumptives is employed.

16. Bloodless Reposition of Congenital Hip-joint Dislocation.—Mueller publishes the results obtained by Lorenz in 33 cases of congenital hip-joint dislocation by means of bloodless reposition to show that it is the best method of treatment of congenital dislocation of the hip and that Lorenz's promise of 50 per cent. anatomic cures is not too optimistic.

23 *Ununited Fracture of the Humerus Treated by the Bolt Method—Failure of Union—Subsequent Successful Wiring. H. W. Jones, St. Louis, Mo.

19. Papilloma of Larynx in Children.—According to Clark, papilloma of the larynx in children is a very serious condition. The best method of treatment in all cases is tracheotomy and non-interference with the growth. If, under this treatment, it still persists after an age when the child can be treated as an adult, it has probably lost its activity of reproduction and attempts at its removal may be made. Clark cites 14 cases, 9 boys and 5 girls. One case dated from birth. In another case the symptoms began at the age of 3 months. Five other patients were 2 years old or under when they first showed evidence of laryngeal trouble. Of the remainder, one was 3 years old, one 4, two 5, one 6 and two 8 years old when the first symptoms appeared. The time elapsing between the appearance of the first symptoms and application for treatment varied from four months to four years and nine months. In the majority this period was from one to three years. In one case the symptoms began to appear after an attack of measles, in one after whooping cough and in one after grippe. Treatment without previous tracheotomy was attempted in 4 cases. One of these patients died under the operation, one was lost sight of, one operation was successful, and one patient, after several successful operations, required tracheotomy for a sudden attack of dyspnea during an operation. Preliminary tracheotomy was done in the 10 remaining cases. Of these latter, 4 patients died; 3 of bronchopneumonia, and one of suffocation after a difficult second tracheotomy. One of those dying of bronchopneumonia had bronchitis at the time of the operation, which was necessitated on account of severe dyspnea, and one died so long after tracheotomy (eight months) that death can not be directly attributed to that operation. One patient who died of suffocation after a very difficult second tracheotomy necessitated by the recurrence of the growth, illustrates the importance of not removing the tube until there is no vestige of papilloma or until the child is old enough to be treated as an adult.

20. Muscle Transference.—Bradford cites six cases in support of the contention that silk suture can be made to serve as a tendon mechanically, and may also be the basis of the organization of new strong fibrous tissue, thus creating a new tendon. It is necessary, however, that the muscle which is to be cut should not be left in a relaxed condition. If a strong muscle is inserted into a weak muscle it is essential not only that the insertion should be strong, but that the tendon into which the insertion is made should be so disorganized by paralysis as to become stretched when subjected to use. The transferred muscle should be attached in such a way that its contraction can be functionally effective, and it should be inserted into such a point as will render its contractions efficient.

23. Treatment of Ununited Fractures.—Although not advocating the abolition of the mortise joint as unsurgical, Jones believes that if union of bone occurs by simply apposing bone ends, much time and labor is wasted by carefully mortising bones together, especially as the latter proceeding is open to two risks—breaking of the wires during application of the dressings, and subsequent necrosis from pressure or tension. Jones considers the employment of a steel or silver bolt undesirable.

30 *Preliminary Notice of a Modification of the Guaiac Test for Blood. I. S. Wile, New York.

30. **Modification of Guaiac Test for Blood.**—Wile describes his test as follows: To equal parts of chloroform and turpentine tincture of guaiac (U. S. P.) is added, a drop at a time, until slight milkiness appears. To one or two cubic centimeters of this reagent the suspected solution is added and the mixture is thoroughly shaken. In the presence of blood the chloroform-turpentine-guaiac solution becomes blue. The color takes a few seconds to manifest itself, but gradually deepens until all the hemoglobin has entered into the reaction. The color then gradually becomes lighter and slowly disappears. This chloroform modification gives a clearly cut reaction, and is more delicate than the simple peroxid of hydrogen and guaiac reaction. The solution, if kept in an amber-colored container, will keep for several days without losing its power to give the reaction. Instead of using tincture of guaiac, a 10 per cent. solution of resin of guaiac in glacial acetic acid may be substituted.

44. **Treatment of Fractures.**—Warbasse says that the first and most important thing in the treatment of a fracture is that the surgeon should have a mental picture before him of the conditions of the bone which he is treating. He believes that the old methods of diagnosis are still the best, and that there is no short cut to the acquirement of skill. Practice and experience are still the best teachers. He deplores the fact that the young practitioners are blunting their diagnostic senses by a too great dependence on the *x*-rays, which in most cases, Warbasse thinks, should be used not to make the diagnosis, but to confirm it. If this were done, surgeons would be better equipped for work in places where the *x*-rays is not available. He calls attention to the diagnostic significance of crepitus, the importance of which, he thinks, is often overrated, while local tenderness and pain are apt to be overlooked. There are certain obstacles which may prevent the easy and satisfactory reduction of a fracture, and of these the chief are muscular contraction and pain, both of which are overcome by general anesthesia. Warbasse condemns the method of correcting displacements by tiring out contracted muscles by making continuous extension against their contractile force, and states that, in his opinion, immediate and complete reduction is the proper procedure. The surgeon should not rest until the fractured bone is in the position in which he wishes it to heal. He believes that fomentations of lead, opium or other similar preparations have little or no place in the treatment of fractures. The best treatment is the correction of the deformity. When a point of bone lies close to the skin and threatens to perforate it a compressing pad should be placed not over the threatening point, but over the bone a short distance away. If a fracture involves a joint or is in close proximity to the tendon sheaths, another element of importance is introduced. If the joint is kept immobilized too long, the plastic material becomes adherent to the opposite bone surface. The amount of this plastic substance is dependent on the degree of traumatism; in other words, on the degree of separation and mobility of the fragments. Motion of the joint immediately after the injury increases the amount of exudate. Too prolonged immobilization of the joint threatens ankylosis. After from ten days to two weeks, when traumatic reaction has subsided, passive motion should be instituted. Warbasse believes that more harm is done by the anxiety to secure firm bony union than by the too early employment of passive motion. In dressing a fracture of the lower extremity, he states that the patient should be laid on a flat, unyielding surface and should not be allowed to watch the operation. He describes, in detail, the usual method of applying a plaster cast, and says that ordinarily too much bandage is applied. In applying a cast the important thing is that the inside be free from irregularities and that the pressure be even throughout. A properly applied cast gives a sense of comfort and support. A cast that is not comfortable should not be left on. Warbasse concludes his article by stating that the methods we now have at our command for accurately determining the condition of broken bones and for the correction of displacements and the relief of complications places modern surgery in a position to be satisfied with nothing but good results in the treatment of fractures.

53. **Venereal Prophylaxis.**—Carrier calls attention to the importance of preventing the spreading of venereal diseases, and states that marriage of individuals suffering from any venereal affection should be prohibited by law. He concludes his article with the following statements: Venereal diseases exist in every community to such an extent that an imperative demand is made for prophylaxis. While legal restrictions are of immense value, their enforcement at the present time is impossible. The laws regarding the issuing of the marriage license should take account of venereal diseases. Venereal diseases should be regarded as contagious and reportable to health boards. Hospital accommodation should be furnished for those suffering from venereal diseases. Efforts for the present should be along the line of education in the family, in the schools, and by literature and lectures to the public. Medical pessimism in this matter of prophylaxis must be eliminated.

55. **Method for the Withdrawal of Pleural Effusions.**—Donald and Mercer have devised an apparatus for the removal of pleural effusions. The apparatus is very simple. It consists of two wide-mouthed bottles, stoppered by either rubber or cork, through which are inserted tubes of metal or glass which connect with an ordinary fountain syringe tube. The bottles for accurate work may be graduates so that the amount of fluid withdrawn and the amount of air reinserted can be measured. A bottle has three tubes running through the cork; one extending nearly to the bottom is connected to a similar one in

bottle B with a rubber tube about four feet in length; the other two extend just through the cork, one of them being connected to a short glass tube filled with sterile absorbent cotton, and the other with a tube leading to the needle. Bottle B has two tubes; one, as in bottle A, reaching nearly to the bottom, and the other, a short one, may be used to withdraw the overflow, or by the attachment of an aspirator pump to obtain greater suction pressure on the other bottle, that is, on the fluid which is being aspirated. This, however, is rarely necessary. All the pressure that is desired can be secured by lowering the second bottle and so increasing the syphon pressure. The bulb is convenient when filling bottles, but must be detached when the instrument is used. The tubes leading to the needle and air filter and between A and B are controlled by wire clips. Clips from fountain syringes, a couple of large empty tablet bottles, three or four glass medicine tubes, some rubber syringe tubing, and an old antitoxin syringe constitute the paraphernalia necessary for the manufacture of this apparatus by a physician himself. The rubber corks make more perfect joints, and so constitute a more perfect apparatus, but the authors have used the other and more simple form of apparatus and have found it to work satisfactorily. The following directions for use are given: Fill both bottles slightly more than half full of sterile water; insert the tubes until the water fills bottle A with the three tubes and flows from the aspirating needle, then close clip on that tube and lower bottle B, open clip on air filter, and leave it open until bottle A is about two-thirds full of filtered air, then close clip on air tube, and the apparatus is ready for use. Insert the needle in the selected spot on the affected side, open clip on the needle tube, and the pleuritic fluid will immediately flow into bottle A and over into bottle B. When about eight ounces, or 250 c.c., have been withdrawn, raise bottle B and the water will flow back into bottle A, forcing the filtered air in it through the needle into the pleural cavity. By repeating the process, opening the air filter, and refilling bottle A as necessary, the fluid can be withdrawn and replaced by an equal measured quantity of filtered or sterilized air. If it is desired, the cotton in the tube can be impregnated with formaldehyd and the pleural cavity can be filled up with this form of air. As formaldehyd is decidedly irritating in its qualities, only a very small quantity of the medicament must be introduced. Bottle B can be emptied as filled by shutting off the flow from bottle A and pouring out the fluid contained in it; or it can be allowed to run out through the overflow tube on B into another bottle or vessel. It is considered hardly necessary to replace the fluid with an exactly equal amount of sterilized air, although a liberal amount should be introduced in order to procure a thorough emptying of the pleural cavity. After that has been done, the operator can use his own discretion as to whether he will allow the air to remain in the pleural cavity or will withdraw a small portion of it. The advantages of the operation can be summed up as follows: 1. All the fluid can be withdrawn at once. 2. There is no pain and no distress, except from the introduction of the needle, through the whole operation. 3. The lung is splinted by the cushion of sterilized air and is permitted to expand only very slowly. 4. The air pressure prevents the leaking of fluid through the cells back into the pleural cavity and the reaccumulation of the fluid there. 5. The apparatus can be improvised by any physician or can be manufactured at a very low figure by any instrument manufacturer. 6. It is believed to be especially adapted to cases of old effusion in which the withdrawal has been postponed for a long time, and cases in which there is a tendency toward the reaccumulation of the fluid.

64. **Therapeutic Value of X-Ray.**—Foster details his experience with the *x*-ray in the treatment of tuberculosis of the skin and of glands, acne, sycosis, eczema, pruritus, psoriasis, and exophthalmic goiter. He is of the opinion that deep-seated malignant disease should never be treated by the *x*-ray until the resources of surgery have either been exhausted or refused by the patient. Patients suffering from inoperable malignant disease should be given the benefits of *x*-ray treatment because it usually is followed by improvement, with the possibility of cure.

65. **Carbolic Acid in Surgery.**—Stewart calls attention to the uses of carbolic acid, i. e., the liquidified crystals, in the cure of hydrocele and other cystic processes by the injection of small amounts of the pure acid without the use of alcohol. The acid is also of service in various chronic serous inflammations of the bursa and tendon sheaths. Its use as a sterilizing agent for instruments and septic wounds is also referred to. Stewart says that in all acute suppurative processes the course of the disease may be shortened and extension averted by free incision, followed by the application of carbolic acid and alcohol. In all tubercular softenings the use of carbolic acid and alcohol after evacuation of a cavity permits of the closure of the cavity without establishing drainage, thus expediting healing. Many other uses of the acid are mentioned by Stewart in the hope that the profession will again give to this remedy the place it deserves as a therapeutic agent.

67. **Medical Organization.**—As evils demanding the organization of the medical profession Taylor mentions patent medicines, quacks, the various sects and fads and healers of all sort, the existence of too many cheap, superficial, ill-equipped diploma mills, called colleges, which are yearly turning out hordes of graduates who are not properly qualified, the so-called contract or club practice, and the encroachments of other organizations. All these evils, he considers, may be eradicated by a perfect organization. The objects to be gained by organization are: 1. To protect the public from all those who profess or advertise to treat or to cure mental or physical infirmities, or to sell remedies for those conditions, and are not properly qualified to do so. 2. To secure uniform legislation to keep the field properly belonging to the medical profession free from intruders. 3. To secure high uniform standards for the regulation of practice in the various states, and to see that these laws are enforced. 4. To check evil tendencies and pernicious practices among physicians. 5. To elevate the requirements of medical education so that the numerous small, poorly equipped and inefficient medical schools shall be wiped out. 6. To stimulate and to foster a desire for scientific research and medical advancement in the profession. 7. To promote and to establish public health relations. 8. To promote a professional, fraternal and friendly feeling among physicians by more intimate contact, frequent meetings and social intercourse. 9. To increase revenues and to establish resources for the needs of professional advancement. The history of medical organization and the condition of the Montana State Association are also discussed, as well as the duties and functions of state organizations. Taylor feels that state societies do not stand close enough to the county societies and other affiliated societies, and suggests ways and means for accomplishing the desired results.

68. **Pneumonia Complicating Surgical Operations.**—Rothrock reviews the literature relating to this condition and cites cases. He states that as preventive measure, it should be a fixed rule that no patient who has at the time an acute coryza, tonsillitis or bronchitis should be given an anesthetic, except in case of absolute necessity. Not only is it desirable under such circumstances to avoid the irritant effect of the

por of the anesthetic, but under such conditions there is kely to be an increased virulence of the micro-organisms in e air passages. Ether should be given in the least possible ncentration, and, to avoid aspiration of the secretions of e mouth, the patient's head should be kept low and turned one side, in order to allow the secretions to flow out of the outh. Previous to the administration of the anesthetic the outh should receive attention and the teeth should be care-lly cleansed, after which an antiseptic mouth wash should e liberally used. The stomach should be empty, and in case f operation on that organ, lavage should precede the opera-ion. If necessary to use chloroform in the presence of gas or mp light, the room should be well ventilated. In case of eak circulation, it is very desirable to prevent hypostatic ongestion. Such patients should have their position fre-uently changed, and as soon as possible should be raised the half-sitting posture. The importance of meteorism as factor in hypostatic congestion should not be lost sight of. istention of the stomach embarrasses the heart's action by ressure and also encroaches upon the lower lobes of the ngs, preventing their full expansion. It should be relieved y re-establishment of intestinal peristalsis as early as pos-ible after the first twenty-four hours following the opera-ion. Following Czerny's suggestion, the patient should be urged o expand the lungs fully, even though the effort is painful, o further aid in the prevention of hypostasis.

77. **Congenital Dislocation of the Hip.**—Ridlon discusses the se of the Bartlett machine for the reduction of congenital islocations of the hip. The machine consists of an iron framework bolted to a table. The patient's hips rest on the framework, with an adjustable saddle between the legs for fixative counter traction. Below (back of) each hip are strong pins, or pegs, and at each side of the hips are similar pins or pegs made adjustable by set screws; to these pins or pegs may be attached a device giving motion in abduction, adduction, flexion, extension and rotation, that carries a long traction rod. The traction is made by the conventional windlass device below the foot acting on a strap that has been passed around a padded boot on the patient's ankle. The device for motion in all directions at the hip is the original and interesting part of the machine. Bartlett calls it an "eccentric cam." A solid cylinder, with a hole near its periphery, is passed on over the pin or peg; this by a removable wrench gives an eccentric movement to press the head of the femur inward, or add to the downward pull. Around the cylinder passes a collar; this gives abduction or adduction. Attached to the collar is a hinge joint, giving flexion and extension. From this joint passes a pin that plugs into the end of the extension bar, giving rotation motion. Above the first cylinder, when placed on the pin at the side of the hip, is a second solid cylinder set in the same eccentric manner as the first and surrounded by a collar carrying the "deflector," which is worked by a handle. With the wrench on the cylinder and the handle on the deflector pressure can be made downward, inward or upward (forward), or in all directions at the same time against the greater trochanter and neck of the femur. Ridlon believes that this machine is a good and useful appliance, but the fact that it is patented and the terms demanded by the inventor, prohibit its extensive use. The use of the machine on patients who have relapsed into dorsal, anterior, supracotyloid, subpinous, or any possible position does not seem to give as satisfactory results as when used in virgin cases. It is, like all other operative procedures, more difficult when one has tried and failed by some other method, and in patients who have been partially operated on and in those who have been allowed to relapse through lack of proper after treatment.

86. **Appendicitis.**—Beyea directs attention to the value of routine abdominal auscultation as a means of determining the absence or presence of peritoneal infection in acute appendicitis, and also describes a method of abdominal drainage applicable in certain suppurative cases, and a modification of the operative technic which facilitates the operation, shortens its duration, and lessens the danger of peritoneal infection. He says that if the clinician will auscultate, preferably with the thickness of a towel separating the naked ear from the abdominal wall, over the healthy abdomen of several individuals, he will note, occurring at irregular intervals of two, five or ten seconds, the characteristic normal, soft, small, peristaltic sounds. With practice, and subjected to a greater or less variation recognized within the normal, his ear will become more and more familiar with the normal sounds until a distinct degree of accuracy is obtained. With the extent and intensity of peritoneal infection the sounds will occur at longer intervals, of from a half minute to a minute or longer, and their character will be changed from a soft murmur to a more pronounced gaseous sound or the sound of fluid or gas suddenly passing an obstruction. In the case where general peritonitis is present, no sound will be heard or only a single sound after a long interval. When the peritonitis is localized to an area the frequency of sounds, in most cases, is generally diminished, particularly over the affected area. Beyea recommends the special form of rubber covered gauze Mikulicz abdominal drain for application in certain of the cases of periappendicular suppuration devised by Dr. Charles B. Penrose. It is composed of a gauze bag six or seven inches in length and from an inch to an inch and a half in diameter when distended. Attached to the closed end of the bag is a silk ligature. Within the bag are placed side by side three or four gauze wicks, each composed of a few layers of gauze folded into a wick. The gauze bag is covered by an envelope of very thin rubber, the rubber bag being a condom, the closed end of which has been cut off. The gauze bag containing the wicks of gauze should extend a short distance beyond the rubber envelope as is shown in the illustration. The gauze portion of the drain is sterilized with the dressings, the rubber envelope by boiling in water. The ligature is attached for the purpose of assisting in the removal of the drain, traction being made on that portion in contact with the area to be drained. The gauze wicks should be placed rather loosely in, just filling, the bag. Beyea's modification of Dawbarn's technic is carried out by employing a specially made hemostatic forceps. The instrument is of the general shape of the small-sized Kelly curved hemostatic forceps. The biting or contact surfaces of the blades are made with two shallow furrows and elevations, corrugations, running lengthwise. The forceps are further made so that when closed, fixed at the first notch, the last half-inch is perfectly round and gradually tapers to a small blunt point. The technic is identical with that described by Dawbarn up to the point of removing the appendix, i. e., the mesoappendix is ligated and cut to the wall of the appendix, and the purse-

six inches. Strong silk sutures were passed on either side of the upper part of the incision to serve as guides, and the volsella were removed. By bimanual manipulation the head was pressed into the pelvic brim; the membranes were then ruptured, the forceps were applied to the head, and the child delivered, the cord being immediately clamped and divided. The uterus was then again drawn down by the strong silk sutures that had been applied for the purpose, and without waiting to deliver the placenta, the median incision was continued until, with the help of traction from below and pressure by an assistant from above, the uterus was delivered. Forceps were applied to the broad ligament on either side and to the posterior vagino-peritoneal attachment, the tissues being divided successively as the forceps were applied. After the uterus had been removed in this way the forceps were allowed to remain, a long strip of iodoform gauze being introduced into the bottom of Douglas' pouch and another being packed round between the bundle of forceps and the wall of the vagina. The child was livid when extracted, but was easily resuscitated and lived. The mother's recovery from the operation was uneventful, but a year later her physician reported that she was very weak, thin, anemic, and suffering from diarrhea, alternating with constipation. There was also an offensive bloody discharge from the vagina. The pelvis was occupied by a large, hard nodular mass which descended low in the vagina and rose two and a half inches above the pubic arch. In the second case the woman's age was 29. A similar operation was performed and the patient made an excellent recovery. In this case also the child was partially asphyxiated, but was resuscitated. Wilson states that in both these cases the immediate result of the operation left nothing to be desired. The children were delivered alive and thrived so long as they were kept in the hospital, their subsequent deaths being due to carelessness and neglect on the part of the mothers. He states that his experience in these two cases shows that vaginal Cesarean section, even in the last months of pregnancy, is not a difficult one in suitable cases, that the immediate risk to the mother is not great, and that the chances for the child are good. The value of the proceeding, however, depends on the remote results as regards the reappearance of cancer, and until these can be estimated and compared the question of the best method of operating remains an open one.

6. **Complications of Uterine Fibromyomata.**—Cameron reports illustrative cases and discusses at length the various degenerations and complications which may take place in these growths. He says that while some authorities deny that sarcomatous changes can take place in fibromas of the uterus a careful review of reported cases compels one to admit that they may occur. A point of some interest in sarcomas of the uterus is that they may be shelled out exactly like a fibromyomata. He quotes statistics to prove that the association of adenocarcinoma of the uterine body with fibroids is more than a mere coincidence, and states that a fair average would be from 2 to 3 per cent. Carcinoma of the vaginal portion of the cervix with uterine fibroids is the most common variety. A frequent accompaniment of uterine fibromyomata is a marked increase in the size of the uterine and ovarian arteries, which, in well-marked cases, may approach the carotid in size. They are often greatly increased in length and become exceedingly tortuous. Microscopically, the circular and longitudinal coats are seen to be very much hypertrophied and in some cases there is a tendency to excess of fibrous tissue in the internal coat. Cystic degeneration in fibroids is a fairly frequent occurrence, according to Cameron, and may take place in young women or in women many years past the menopause. The cystic changes may be either diffuse or localized. One of the earliest changes in the histogenesis of cystic fibroids, he states, is a disappearance of the nuclear staining in the connective tissue. The fibers then seem to swell and disappear and the muscle cells are affected secondarily. Such progressive changes may give rise to spaces of large size, the walls of which resemble somewhat the interior of the heart cavities through the projection into them of the relatively unaltered muscular tissue. Cameron states that it is a curious fact that many broad ligament tumors undergo myxomatous change and says that recently he found this change in a spindle-celled sarcoma growing in the broad ligament. He refers to torsion of the pedicle in subserous myomata of the uterus with consequent displacement of that organ, and in some cases omental adhesions. He reports briefly a case of fibromyomatous polyp complicating a three months' pregnancy. The tumor was removed, but the patient aborted immediately after. Examination of the tumor after removal led Cameron to believe that when a submucous fibromyoma is extruded into the vagina and pregnancy supervenes the so-called mucous membrane may undergo changes analogous to those in the uterus. He refers briefly to fibroids complicated with tuberculous disease of the ovaries and tubes and to adenomyomata of the uterus.

9. **Prolapsus Uteri.**—Parsons reports on the results obtained in 93 cases of prolapse of the uterus with the operation introduced by him, consisting of the injection of the broad ligament with a solution of 12 grains of sulphate of quinin dissolved in 30 minims each of distilled water and dilute sulphuric acid. The idea is to cause an effusion of lymph in the utero-pelvic band within the broad ligaments so that repair will take place. There is no rise of temperature, no inflammation, no pain accompanying this procedure. It can be done anywhere and in a few minutes. The patient is prepared for the operation by douching the vagina with bichlorid of mercury, 1/2000. The bowels are thoroughly emptied and an enema is given the morning of the operation. Depending on the severity and duration of the prolapse, the patient is kept in bed for from one to seven days, and, if necessary, the uterus must be held in place with the pessary. Eighty per cent. of the patients treated had complete procidentia, some of them for many years. There was great improvement in nearly all the cases, and only one entire failure. About 80 per cent. are completely relieved of their prolapse. Six patients have born children since the operation and have not had any recurrence of the procidentia, although the uterus was a little lower after confinement than it was before. Recurrence of the prolapse took place in three cases after operation, and in one case after five months as the result of much coughing.

13. **Fracture of Patella.**—For the past eight years Moullin has wired every case of fracture of the patella, with one exception, no matter what the size of the fragments, whether or not they were comminuted or whether the patients appeared to be on the verge of delirium tremens. The one exception was a case of refracture in an enormously stout woman in whom no operation of any kind was advisable. The operation was performed on the third or fourth day after the accident. A semicircular flap is raised from over the fragments and all the blood clot is carefully turned out. Each fragment is drilled in such a way that the wire does not project through the cartilaginous surfaces. A single stout silver wire is passed through and the ends are twisted together until the fragments are in exact apposition, cut short, and buried. No carbolic acid or other antiseptic is allowed to touch the interior of the joint. There is no occasion to wash it out, as the blood, being all coagulated, can be removed with ease by means of a scoop and forceps. The torn fascia on the cutaneous surface of the patella is then united with catgut and one or two catgut sutures are used to join together the aponeurosis on either side if it has been extensively lacerated. No drain is inserted, but the angle of the cutaneous incision is left a little open in case there should be any oozing. No splint is used. Deep and superficial dressings are applied and the knee is firmly bandaged.

string suture is introduced through the walls of the cecum and is made ready to be tied. The curved forceps described are then made to grasp the appendix at a point about a half-inch from its base. The appendix is then cut away flush with the upper surface of the forceps. Then, catching the near-by peritoneal surface of the cecum with rat-toothed forceps, the grasp of the curved forceps is loosened, but still grasping the center of the stump (closing the opening into the cecum), it is turned to an angle parallel with the opening in the appendix. With the forceps in this position the stump end is inverted into the cecum, the instrument's grasp is easily loosened and the instrument removed, while the purse-string suture is securely tied by an assistant. A running silk suture placed over the position of the purse-string completes the operation.

91. Unilateral Syringomyelia.—Herbert reports the case of a child 5 years old that presented symptoms of unilateral syringomyelia, as well as spontaneous necrosis of four toes which ended in self amputation. The child had been healthy until 3 years of age, at which time there appeared on the third right toe a painless panaritium, in the progress of which a piece of bone became separated and fell off. After about three months spontaneous healing of the bone process took place with the loss of this toe. Later a similar process occurred in the second, fourth and fifth toes. The right leg, especially the right foot, exhibited marked disturbances of sensibility. There was a disassociation anesthesia, trophic changes and muscular atrophies, all pointing toward syringomyelia.

8 Case of Elephantiasis of the Vulva in Association with Elephantiasis of the Right Lower Limb. E. J. Maclean.
9 *Further Report on a New Operation for Prolapsus Uteri. J. I. Parsons.

1. Cancer of the Uterus.—Since the autumn of 1898 Wertheim has operated in all cases of carcinoma affecting the cervix and portio vaginalis by the abdominal route in such a way that by freeing the ureters and separating the bladder and rectum he has removed the cancerous uterus, together with a great deal of the surrounding cellular tissue and lymph glands. The operation, with which all surgeons are familiar, is described in detail. Wertheim considers extensive vaginal operations more difficult than extensive abdominal ones, and believes that there is no difference between the mortality of the two operations. In spite of all skill and technic, the vaginal operation does not permit of so much of the parametrium being removed as does the abdominal, nor does it permit of the removal of the glands which lie on the iliac vessels.

3. Cancer of the Cervix in the Last Two Months of Pregnancy.—Wilson reports two cases of cancer of the cervix complicating pregnancy in which vaginal Cesarean section was performed. In the first case the patient was a woman, aged 32, and the operation was performed at the end of the eighth month. When first examined, a pedunculated growth was observed attached to the posterior lip of the cervix; this growth was removed under anesthesia and the posterior lip of the cervix was curetted. One week later the uterus and its contents were removed. A transverse incision was made through the anterior attachment of the vagina to the cervix, and the bladder was pushed upward; the anterior wall of the cervix was divided in the middle line, the edges of the incision were pulled down by volsella on either side, the bladder was pushed further upward, and the median incision prolonged for about six inches. Strong silk sutures were passed on either side of the upper part of the incision to serve as guides, and the volsella were removed. By bimanual manipulation the head was pressed into the pelvic brim; the membranes were then ruptured, the forceps were applied to the head, and the child delivered, the cord being immediately clamped and divided. The uterus was then again drawn down by the strong silk sutures that had been applied for the purpose, and without waiting to deliver the placenta, the median incision was continued until, with the help of traction from below and pressure by an assistant from above, the uterus was delivered. Forceps were applied to the broad ligament on either side and to the posterior vagino-peritoneal attachment, the tissues being divided successively as the forceps were applied. After the uterus had been removed in this way the forceps were allowed to remain, a long strip of iodoform gauze being introduced into the bottom of Douglas' pouch and another being packed round between the bundle of forceps and the wall of the vagina. The child was livid when extracted, but was easily resuscitated and lived. The mother's recovery from the operation was uneventful, but a year later her physician reported that she was very weak, thin, anemic, and suffering from diarrhea, alternating with constipation. There was also an offensive bloody discharge from the vagina. The pelvis was occupied by a large, hard nodular mass which descended low in the vagina and rose two and a half inches above the pubic arch. In the second case the woman's age was 29. A similar operation was performed and the patient made an excellent recovery. In this case also the child was partially asphyxiated, but was resuscitated. Wilson states that in both these cases the immediate result of the operation left nothing to be desired. The children were delivered alive and thrived so long as they were kept in the hospital, their subsequent deaths being due to carelessness and neglect on the part of the mothers. He states that his experience in these two cases shows that vaginal Cesarean section, even in the last months of pregnancy, is not a difficult one in suitable cases, that the immediate risk to the mother is not great, and that the chances for the child are good. The value of the proceeding, however, depends on the remote results as regards the reappearance of cancer, and until these can be estimated and compared the question of the best method of operating remains an open one.

6. **Complications of Uterine Fibromyomata.**—Cameron reports illustrative cases and discusses at length the various degenerations and complications which may take place in these growths. He says that while some authorities deny that sarcomatous changes can take place in fibromas of the uterus a careful review of reported cases compels one to admit that they may occur. A point of some interest in sarcomas of the uterus is that they may be shelled out exactly like a fibromyomata. He quotes statistics to prove that the association of adenocarcinoma of the uterine body with fibroids is more than a mere coincidence, and states that a fair average would be from 2 to 3 per cent. Carcinoma of the vaginal portion of the cervix with uterine fibroids is the most common variety. A frequent accompaniment of uterine fibromyomata is a marked increase in the size of the uterine and ovarian arteries, which, in well-marked cases, may approach the carotid in size. They are often greatly increased in length and become exceedingly tortuous. Microscopically, the circular and longitudinal coats are seen to be very much hypertrophied and in some cases there is a tendency to excess of fibrous tissue in the internal coat. Cystic degeneration in fibroids is a fairly frequent occurrence, according to Cameron, and may take place in young women or in women many years past the menopause. The cystic changes may be either diffuse or localized. One of the earliest changes in the histogenesis of cystic fibroids, he states, is a disappearance of the nuclear staining in the connective tissue. The fibers then seem to swell and disappear and the muscle cells are affected secondarily. Such progressive changes may give rise to spaces of large size, the walls of which resemble somewhat the interior of the heart cavities through the projection into them of the relatively unaltered muscular tissue. Cameron states that it is a curious fact that many broad ligament tumors undergo myxomatous change and says that recently he found this change in a spindle-celled sarcoma growing in the broad ligament. He refers to torsion of the pedicle in subserous myomata of the uterus with consequent displacement of that organ, and in some cases omental adhesions. He reports briefly a case of fibromyomatous polyp complicating a three months' pregnancy. The tumor was removed, but the patient aborted immediately after. Examination of the tumor after removal led Cameron to believe that when a submucous fibromyoma is extruded into the vagina and pregnancy supervenes the so-called mucous membrane may undergo changes analogous to those in the uterus. He refers briefly to fibroids complicated with tuberculous disease of the ovaries and tubes and to adenomyomata of the uterus.

9. **Prolapsus Uteri.**—Parsons reports on the results obtained in 93 cases of prolapse of the uterus with the operation introduced by him, consisting of the injection of the broad ligament with a solution of 12 grains of sulphate of quinin dissolved in 30 minims each of distilled water and dilute sulphuric acid. The idea is to cause an effusion of lymph in the utero-pelvic band within the broad ligaments so that repair will take place. There is no rise of temperature, no inflammation, no pain accompanying this procedure. It can be done anywhere and in a few minutes. The patient is prepared for the operation by douching the vagina with bichlorid of mercury, 1/2000. The bowels are thoroughly emptied and an enema is given the morning of the operation. Depending on the severity and duration of the prolapse, the patient is kept in bed for from one to seven days, and, if necessary, the uterus must be held in place with the pessary. Eighty per cent. of the patients treated had complete procidentia, some of them for many years. There was great improvement in nearly all the cases, and only one entire failure. About 80 per cent. are completely relieved of their prolapse. Six patients have born children since the operation and have not had any recurrence of the procidentia, although the uterus was a little lower after confinement than it was before. Recurrence of the prolapse took place in three cases after operation, and in one case after five months as the result of much coughing.

19 Question of a Medical Training for Natives of South Africa. N. MacVicar.

13. **Fracture of Patella.**—For the past eight years Moullin has wired every case of fracture of the patella, with one exception, no matter what the size of the fragments, whether or not they were comminuted or whether the patients appeared to be on the verge of delirium tremens. The one exception was a case of *refracture* in an enormously stout woman in whom no operation of any kind was advisable. The operation was performed on the third or fourth day after the accident. A semicircular flap is raised from over the fragments and all the blood clot is carefully turned out. Each fragment is drilled in such a way that the wire does not project through the cartilaginous surfaces. A single stout silver wire is passed through and the ends are twisted together until the fragments are in exact apposition, cut short, and buried. No carbolic acid or other antiseptic is allowed to touch the interior of the joint. There is no occasion to wash it out, as the blood, being all coagulated, can be removed with ease by means of a scoop and forceps. The torn fascia on the cutaneous surface of the patella is then united with catgut and one or two catgut sutures are used to join together the aponeurosis on either side if it has been extensively lacerated. No drain is inserted, but the angle of the cutaneous incision is left a little open in case there should be any oozing. No splint is used. Deep and superficial dressings are applied and the knee is firmly bandaged.

On the third or fourth day the bandages and the superficial dressings are removed and are replaced by a lighter bandage, and the patient is encouraged to flex and to extend the limb more and more each day until by the end of two weeks it can be bent to a right angle. Massage is begun as soon as the wound is healed. The patient is allowed to get up before the end of the third week, and by the end of the fourth he is able to walk without a limp and to kick. In one instance bicycle riding was resumed before five weeks had elapsed from the date of the accident without any ill results.

18. Treatment of Tetanus by Spinal Anesthesia.—Russell reports a case of tetanus treated successfully by subdural spinal injections. Sixteen c.c. of cerebral fluid were withdrawn and 3 c.c. of the following solution were injected: One and a half grains of B. eucaine, one-third of a grain of morphin sulphate and three grains of sodium chlorid, with sufficient water to make three and a half ounces. This procedure was repeated four times.

29. Fibroma Molluscum.—Noyes gives the history of five cases observed among 5,000 consecutive cases of skin affections and concludes as follows: 1. The so-called molluscum fibrosum growths arise from branches of the cutaneous nerves, by proliferation of the endoneurium. 2. The new tissue may remain confined by the perineurium for a period, or it may break away and become diffused at quite an early stage, spreading into the adjacent tissue surrounding any or all of the structures of the corium and subcutaneous tissue, including altered nerve branches themselves, which are still confined by the perineurium. 3. The proliferation of the endoneurium, and the consequent disappearance of the nerve fibers and their axis cylinders, leads to more or less loss of sensation in the cutaneous surface overlying the new tissue. 4. Similar changes in the nerves composing the vasomotor apparatus of the cutaneous vessels involved in the new growth may account for the clinically observed discolorations in connection with them. 5. The small nodular projections, due to proliferating endoneurium confined by perineurium, may occur in the smaller nerve branches, giving, microscopically, a neurofibroma-like appearance, without being clinically recognizable as such.

30. Rye Bread in Diabetes.—Lidwill was led to the use of rye bread in diabetes by the craving and empty feeling of which patients on the so-called diabetic diets complained. He found that rye bread is satisfying, stopping that empty feeling, and that patients eat but little of it in proportion to wheat bread, about a loaf and a half sufficing for a week. It contains but little digestible starch; it is laxative; the sugar in the urine diminishes considerably during its use; patients do not tire of it, and it is cheap. Its greatest use is in the milder forms of glycosuria occurring in the middle-aged or old.

37. Long Survival After Removal of Osteosarcoma of Humerus.—Jeanbrau describes in detail a case of malignant neoplasm, originating in the humerus, but extending far into the soft parts, which he treated by interscapulo-thoracic amputation, with the survival of the patient for twelve months. The osteosarcoma had evidently been insidiously developing for some time, but had caused no symptoms until the humerus fractured at the point while the patient, a woman of 41, was trying to open an umbrella in a storm. The amputation was by the Berger-Farabeuf technic. This entails the minimum of shock and prevents the generalization of the growth. The preliminary ligature of the subclavian artery and vein also prevents any appreciable loss of blood and diffusion of infectious material from the tumor. Great care should be taken not to pull on the arm, not even touching it, and not shaking the shoulder, thus avoiding embolism. By this means all traction on the spinal cord is avoided, and the operation is no more serious than mere disarticulation of the shoulder.

38. Survivals After Interscapulo-thoracic Amputation.—Further research and analysis of published records have shown that the operative mortality of this operation for malignant new growths, which was 29.16 per cent. before 1887, has dropped to 7.84 per cent. in recent years, and to 5 per cent. or less if the fatalities for which the operation was not responsible are excluded. The average survival is three years, which is a most remarkable showing when we consider that this crippling operation is not accepted by patients except as a last resort in advanced stages of malignant disease, when their resisting powers are at a low ebb. The number of cases on record is now 125 histologically verified and 63 not verified with the microscope, as the diagnosis was unmistakable at the stage of the disease when the operation was performed. Before the year 1887 the number was 35 cases, with 29.16 per cent. mortality, but since that year the mortality has been only 7.84 per cent. in 153 cases. Absolute cure is possible, as 24 of these patients were in good health five years and more since the operation. Küster, Roth and Ochsner have each a patient in good health for more than ten years, Ochsner and Körte others for more than thirteen, and Chavasse others for more than fifteen years after operation. A patient operated on by Ollier in 1884 is in good health to-day, and one of Syme's patients was known to be in good health for twenty-six years. All the cases since 1887 are summarized at the conclusion of the article.

39. Modified Technic of Interscapulo-thoracic Amputation.—Berger here describes 4 new cases of this operation and his latest modification of his original technic. He has performed the operation seven times. He classifies the 129 cases since 1887 according as the lesion originated in the humerus, in the scapula or in the soft parts. When in the humerus, the mortality has been 2.75 per cent. in 73 cases; in the scapula, 25 per cent. in 20 cases of sarcoma, while one operation for a chondroma was followed by recovery. In 35 cases of tumors originating in the soft parts the mortality was 11.24 per cent. These figures indicate the greater seriousness of lesions in the scapula or soft parts in comparison with those in the humerus. It is more difficult to find and to ligate the subclavian and axillary vessels, and, as the muscles are more liable to be involved, the mutilation is more extensive. Recurrence or generalization of malignant tumors in the humerus was observed in only 48.38 per cent., while the proportion was 73.17 per cent. with tumors of other origin. The survival after removal by this technic of sarcoma of the humerus has averaged from nineteen to twenty months in 30 cases; in case of sarcoma of the scapula from thirteen to fourteen months elapsed before recurrence or generalization was observed, and from nineteen to twenty months in case of malignant tumors in the soft parts. Recovery is the rule after removal of a chondroma. Instead of resecting merely the median portion of the clavicle, he now resects the entire sternal portion after dividing the clavicle in the center. Drainage must be thorough, and for this purpose he introduces a large drain through an incision in the belly of the stumps of the serratus magnus and of the latissimus dorsi to drain the blind pouch between them and the thoracic wall. Drain tubes as large as one's thumb are also inserted at each side and corner and at the lowest point of the operative wound, which should be sutured elsewhere. The dressings should be changed every day, withdrawing the drains after from the fourth to sixth day. In his last four cases healing was complete by the tenth day.

Semaine Médicale, Paris.

41 (XXV, No. 38.) **Des sténoses méconnues du pylore dans l'ulcère gastrique* (unsuspected stenosis). Oettinger.
42 **Le signe de Kernig est-il pathognomonique de la meningite?*

41. **Unsuspected Stenosis of the Pylorus.**—Oettinger calls attention to the frequency of unsuspected partial stenosis of the pylorus. He believes that many cases have been diagnosed as gastrosuccorrhea or other anomaly when in reality the trouble was due to partial stenosis accompanying an ulcer near the pylorus. He describes a case which sustains this assumption. The patient was under observation for six years, and yet until the last few months the possibility of stenosis had never been thought of. He had presented stomach symptoms for eleven years. At first they were intermittent, actual crises with intervals of apparently perfect health. Stagnation of food, with hypersecretion and peristalsis of the stomach, were noted even from the first, but the intervals of apparently perfect health caused the first suggestion of stenosis to be dismissed as untenable. The intervals became shorter and shorter, the symptoms of the crises simulating those of gastrosuccorrhea, intermittent at first, but later becoming chronic. The duration of the attacks was variable, sometimes lasting for several days, but always presenting the features of extremely violent paroxysmal pain, coming on two or three hours after the meals, especially at night, and frequently, but not always, terminating in vomiting of an acid fluid or else of food. According as the stomach contents were obtained at different times, the findings varied from those of hypersecretion with stasis, hypersecretion without stasis or intermittent gastrosuccorrhea to findings which seemed to indicate that the motor functions were quite or nearly normal. All the time the real cause of the disturbances had been an ulcer near the pylorus, entailing partial stenosis of the latter. The stomach was frequently found entirely empty, but at other times residual fluid was found in the morning. If this finding is repeated several times, the amount of fluid being over 40 or 50 c.c., the diagnosis of stenosis becomes more probable, even if at other times the stomach is found empty. The occurrence of pyloric ulcer with partial stenosis may be secondary to hyperacid catarrh, which is generally accompanied by hypersecretion and delay in the evacuation of the stomach.

42. **Kernig's Sign.**—An editorial reviews the evidence presented in the last few months in regard to the pathognomonic value of Kernig's sign in meningitis. The conclusions are that this sign does not necessarily imply the involvement of the meninges, but that it is a confirmatory sign in addition to others suggesting the presence of meningitis.

43. **Postlaparotomy Pneumonia.**—Kelling's researches have established, he thinks, that there is a tendency to hypostasis in the lungs, especially in the right lower lobe, after a laparotomy. Aspiration pneumonia occurs more frequently after laparotomies than after other operations, especially pleuropneumonia of the right lower lobe. This occurs most often when the field of operation was infected. The lung becomes infected through the lymphatics passing through the diaphragm. Pneumonia from embolism is also of frequent occurrence. The infection is transmitted from some ligated vein communicating with the vena cava system or by way of the retroperitoneal veins whose lymphatics are connected with those of the mesentery. Sepsis with hypostatic pneumonia can also spread from the abdomen, and infectious thrombi may form at predisposed points of the veins, because the lymphatics of the diaphragm communicate directly with the blood-vessel system. Infection from the air also deserves more attention than has hitherto been accorded. The conditions are more unfavorable during a laparotomy than in almost any other operation. Postoperative pneumonia is due to infection which would not have occurred without the operation. The operation should be performed in a room absolutely free from dust. There should be no talking over the wound, and mouth masks should be worn. It should further be investigated whether diluting the germs by copious rinsing might not attenuate their virulence. It might be well to flush out the abdominal cavity through the laparotomy wound with a stream of water entering elsewhere and pouring out through the wound. Copious ingestion or injection of fluids also promotes the circulation and reduces the danger of embolism. Early movements of the legs are also important to prevent thrombosis. If the legs are varicose, they should be raised high on pillows. He is convinced that the prevention of infection of the field of operation is the main point in preventing pneumonia after laparotomies.

46. **Postoperative Prolapse of Abdominal Viscera.**—Madelung has collected 144 cases from the literature and knows of others, including seven in his own experience, that bring the total to 157. He analyzes them all to learn the causes of the giving way of the cicatrix and of the prolapse. In 29 cases death was the direct result of the prolapse. Those who survive are not exposed to more disturbances than other people, after the prolapse has been corrected. The number of cases in which the cicatrix was abnormally thin was surprisingly small. The prolapse recurred twice in one and three times in another case. Reposition was generally difficult. Narcosis is not necessary for reduction, as the manipulation of the prolapsed intestines is not felt as pain.

53. Spontaneous Rupture of Cicatrix After Fundal Incision.—Schink has observed a case of rupture of the cicatrix after a transverse fundal incision, and has found three similar cases on record. He gives the details of each. His patient had passed through a pregnancy since the incision, and the rupture did not occur until the second pregnancy. The placenta was not attacned near the point of rupture. He thinks that such cicatricial tissue is liable to be less resistant than the rest of the uterus.

56. Resection of Ovary.—Zacharias relates that Menge has succeeded in maintaining menstruation in three women on whom he operated for removal of bilateral ovarian cysts that had substituted the normal ovary. He accomplished this by making an oval incision around the base of the tumor, which he then shells out with his fingers, leaving an oval plate of ovarian tissue not more than 1 or 2 mm. thick at any point. The edges of this plate are then turned in until the raw surface is entirely covered and the tissue is sutured, the resulting roll being shaped something like a sausage, in the place of the normal ovary. This little roll contains the germinal epithelium of the albuginea and a strip of connective tissue. No follicles could be discovered in it, but a few isolated corpora albicantia were found. The three patients exhibited a few symptoms of the artificial menopause immediately after the operation, but they rapidly subsided, and menstruation has been apparently entirely normal since. The patients were from 25 to 34 years of age.

60. Varying Elasticity of Uterine Muscle.—Van Tussenbroek is amazed that the variations in the elasticity of the uterine walls have attracted so little attention. In many text-books it is announced as a sure sign of perforation when the curette can suddenly be pushed in a few centimeters farther than at first. She thinks that this is of frequent occurrence, and that it is merely the result of the sudden relaxation of the elasticity of the musculature under the influence of the curetting or of the preceding tent dilatation. In some instances she has even found the walls so loose and flabby that curetting was impossible, but by waiting for a time they regained their normal elastic retraction. This flabbiness, of course, increases the predisposition to perforation. She gives a number of illustrations and arguments to show that this transient paralysis is probably due to the mechanical irritation and reviews the literature on the subject since van der Mey first called attention to it in 1894.

64. Causes of Destruction of Bacteria in Small Intestine.—Among the conclusions of the experimental research reported is one to the effect that bile, pancreatic juice and intestine juice have no bactericidal action, but form a g[illegible] e me-
-for microbes. The intestinal wall, on[illegible]
certain part is cheap. ruction of ba[illegible]
chyme as occurring in tomach has
he grow nales de l'Institut but if it i
the ba *Last indexed* ey also proli
l wall o. 8.) Les fermen ne peristalsis di
uiaque dans le lait

mucosa of the normal small intestine insures freedom from bacteria throughout this part of the bowels. When the mucosa is inflamed or diseased it is no longer able to accomplish this, while the intestinal juice offers a good culture medium for the bacteria in which they flourish accordingly.

65. Influence of Changes in the Circulation on Composition of the Urine.—The first part of this study is devoted to orthostatic albuminuria. The details of the examination of 17 patients and of a number of normal persons are given in tabulated form for comparison. The findings testify to the fact that orthostatic albuminuria does not positively exclude nephritis, but that a majority of the cases are not of a nephritic, but rather of a cardio-vascular, circulatory nature and origin. Changing from the reclining to the upright position seems to be the cause, not the upright position in itself, as the albuminuria grows less after the individual has been up for some time. The increased concentration of the urine suggests that the circulation through the kidneys is hampered, while the pressure in the veins is higher, and this means venous hyperemia, which can not fail to injure the organ more or less in time, although Posner's patient has exhibited orthostatic albuminuria for many years without evidence of nephritis. Linossier and Lemoine found that the amount of urine was less when their patients were up than when they spent a corresponding twelve hours in bed. The reduction in the output of urine was most pronounced in the patients with some kidney affection.

66. Action of Roentgen, Radium and Ultra-violet Rays on the Blood.—Linser and Helber summarize the results of their experimental studies in the statements that radium and ultra-violet rays have no appreciable influence on the blood, but that the Roentgen rays have an elective destructive action on the white corpuscles. This action is most pronounced in the circulating blood. The lymphocytes are the least resistant to the Roentgen rays. A leucotoxin is generated by the destruction of the white corpuscle, and injection of this leucotoxin into the circulation of other animals has a destructive action on the circulating leucocytes. The leucotoxin produced in the blood after exposure to the Roentgen rays induces an immunity to the leucotoxin in time. After Roentgen exposures, nephritis was frequently observed even when the rays had not been applied directly to the kidney. Rabbits, rats, dogs and pigs were the animals used in the experiments.

68. Utilization of Nitrogenous Foods in Digestive Disturbances.—Roehl's tests failed to show that digestive disturbances prevented the utilization of the nitrogenous elements of the food to an extent sufficient to explain the prostration and loss of weight observed in these cases. The cause of the disturbances in the metabolism can not be sought in the nitrogen assimilation.

69. Bacteriemia in Pulmonary Tuberculosis.—Jochmann asserts that, as a rule, it is impossible to detect bacteria in the blood in progressing cases of pulmonary tuberculosis. When found postmortem, they are due to agonal invasion, when the bactericidal properties of the blood have been lost.

71. Dermographia.—Stursberg examined 90 men, 84 women and 70 children in regard to the response of their skin to a line drawn with moderate pressure and moderately quickly along the skin with the rounded end of a metal pencil holder. The stroke was made on the skin of the chest and upper part of the back, and the interval before redness appeared and before it disappeared was noted. The skin became red in nearly every instance. The redness was slightly more pronounced in the patients with neuroses than in others, but the average was surpassed in some of the patients who were free from neurotic manifestations. Dermographia, therefore, has no appreciable *diagnostic significance.*

78. **Pathologic Fractures.**—Grunert classifies pathologic, spontaneous fractures as those due to local changes in the bones, those due to some general affection and those due to idiopathic fragility. He reviews the literature of each class. There are now 73 cases of idiopathic fragility of bone on record. The influence of heredity is a striking feature of some of the cases, fully 20 out of the 73 showing hereditary transmission. The multiple fractures numbered 113 in Chaussier's cases, 119 in Hondley's and more than 200 in Esquirol's. The tendency to fracture in the idiopathic cases is manifested early. He notes that 45 of the 73 cases were observed in England or America, and only 28 in Germany, France and Italy. Verchère has reported that young people displaying a tendency to fractures from slight trauma exhibited polyuria with elimination of unusually large amounts of phosphoric acid. It may be possible, Grunert suggests, that a predominant meat diet may alter the composition of the bones in the course of generations so that they may acquire extraordinary fragility, although the diet of the later generations may be entirely hygienic. Further study of the assumed phosphaturia in these cases is necessary to elucidate the still obscure question of the idiopathic tendency to multiple fractures from trifling causes.

79. **Stenosis of Intestine After Reposition of Incarcerated Hernia.**—Meyer reports a case and tabulates those found in the literature in which symptoms of obstruction developed after reposition of an incarcerated hernia. In some cases the symptoms of obstruction persisted either from mechanical obstruction or from functional disturbance of the activity of the intestines; in others the stenosis developed later, after the intestine had been permeable for some time. The details of the latter class are tabulated, thirty pages being devoted to the tables and twenty more to analysis of the cases. He also analyzes the literature on the subject of intestinal hemorrhage after reposition of incarcerated hernia. The danger of tardy stenosis is another reason why forcible taxis should be rejected and herniotomy preferred. Kocher emphasizes the importance of noting whether the arteries in the mesentery of the loop are pulsating as a criterion of the condition of the circulation in the loop. This guards against reposition of a loop destined later to perforate or become gangrenous. The tendency to stenosis seems to be the prerogative of the mucosa. Whether to make an artificial anus or to keep the loop outside the abdomen for a time depends on the individual conditions. The symptoms of tardy stenosis should first be treated on the assumption that they are purely functional, but when this is disproved by their persistence the surgeon should be called for enteroanastomosis or resection, preferably the former. The advantages of resection include microscopic examination of the resected portion which removes all doubt as to the nature of the trouble. If an operation is deemed inadvisable under the circumstances, a temporary artificial anus will relieve and the resection or anastomosis can be made later.

82. **Histologic Examination of 290 Extirpated Superficial Cancers.**—The details of the 290 cases collected between 1901 and 1904 are given in tables with thirteen columns for better comparison. No recurrence has been observed in 111 out of 117 cases in which the cancer was excised into sound tissue, while recurrence has followed in 15 out of 27 in which histologic examination of the edges of the excised portion showed that it did not extend into sound tissue. Borrmann insists that cancer statistics are reliable only when the cases are followed after excision and when histologic examination of the excised tumor shows whether or not the excision was made into sound tissue. He found sound tissue in 81.3 per cent. of the 229 cases of carcinoma of the face, while it was found in only 62.5 per cent. of the cancers removed from the brow and in 70 per cent. of those from the cheek. His experience has been that the percentage is much less in cancers of the tongue and mucosa of the mouth, while it is highest in cancer of the upper lip. The various features of the cases are given with a wealth of details, and the cancers are grouped and classified according to the location, character, course, etc.

85. **Shock in Case of Shot Wounds.**—Schieffer refers to the sudden collapse of dogs when they are hit by shot. It is explainable only by the assumption of shock, as the wounds themselves are not enough to cause death so suddenly. In this article he describes his experiences with dogs under the influence of lumbar anesthesia which seems to attenuate or entirely to abolish the shock. Four out of 5 normal dogs dropped dead when shot, while those under the influence of the lumbar anesthesia survived much longer, although their injuries from the shot were more serious than those of the other dogs.

86. **Cholelithiasis.**—Naunyn remarks that the modern era of cholelithiasis dawned only thirteen years ago. His studies of the natural history of gallstones are based on examination of stones from more than 1,000 cadavers. In all this experience he encountered only ten instances in which there had been an unmistakable dissolving of the stones. They were composed mostly of cholesterin, and the features of the dissolving process observed suggest that it was due to the action of certain bacteria. The action of bacteria is further evidenced by the presence of inorganic lime—phosphate and carbonate—in the stones. Attempts to dissolve the stones by therapeutic measures he does not regard as very promising. The task of internal medicine is to fight the infection of the biliary passages complicating or causing the lithiasis. Nothing is so successful for this as systematic and energetic application of cataplasms to the liver region with hot Carlsbad or similar alkaline-carbonated sodium sulphate water internally. Neither purgatives nor cholagogues are so effectual, according to his experience. He is convinced that it is possible for even a large gallstone to form within a few days or even hours. The Roentgen rays show up well only the stones containing considerable lime. In differentiating cholelithiasis from a stomach affection, the character of the first attack of pain is very important, especially if it occurs in the middle of the night. In this incipient phase the gall bladder is seldom adherent to the pylorus or duodenum. Consequently the pains at first are independent of the taking of food. Later they simulate gastric disturbances. A palpably enlarged spleen is a strong argument in favor of cholelithiasis. Suddenly developing cachexia speaks for cancer in dubious cases. In cases of a fistula into the duodenum, symptoms develop suggesting ileus or diffuse peritonitis. This condition may last for weeks, and when the surgeon is ready to operate the passage of a stone may restore conditions to normal.

87. **Invagination in Children.**—In the 107 cases of invagination reported, the children were well nourished, but habitual constipation seemed to be the rule. The ages ranged from a few months to 8 years. Over 60 per cent. were cur chloroform, taxis and injection of water under Hirschsprung expresses surprise at the compara

number of cases of invagination which he has had occasion to observe, no one else reporting such figures as his. The invaginations in some years seemed to assume almost an epidemic form. The passage of blood-stained stools should warn the mother and physician of the possibility of existing invagination, and the discovery under chloroform of the solid, cylindrical tumor confirms the diagnosis. Digital exploration of the rectus brings away a lot of blood-stained mucus. Under taxis the tumor changes its place and grows smaller and smaller until it finally disappears altogether. Laparotomy had to be performed in 4 cases, 2 of the children recovering. In one of these the invagination was in the small intestine, and reduction was impossible. The abdomen was opened at once, although the child had been brought in during the night, and the invagination was reduced, nine hours after the first symptoms. In the 2 cases in which the children died after laparotomy, five days or fifty-four hours had elapsed after the first symptoms before the children were brought to the surgeon, several days having been wasted on internal measures.

92. **Action of Radium Rays on Various Tissues and Organs.**—Thies has been conducting extensive experimental research on the action of radium rays on living tissues. He has found that it is by no means always a destructive action, but that under certain conditions cell multiplication becomes more lively. The cells of the epidermis proliferate, giving rise to an appearance resembling that observed in cancroids of the skin. The tests were made on tissues and organs of guinea-pigs and mice and on scraps of tissue from Thies' own arm. The vessels proved *exceptionally susceptible to the action of the radium rays*, and this explains their efficacy in curing angioma. Two large angiomata on a child were exposed for an hour to the action of 10 mg. of radium. In the course of two weeks a flat scab formed over the exposed parts, and was thrown off six days later. By the sixth week after the exposure the vessels were no longer visible. In the place of the angioma there was merely a patch of apparently normal skin a *little lighter* in color than its surroundings, but even this difference was scarcely perceptible by the end of six months. In another case a protuberant angioma was exposed for an hour and a half. By the sixth week an insignificant scar was all that was left of the former prominent disfigurement. No spermatozoa were found in the testicles and epididymis of guinea-pigs after the radium had been fastened on the testicle for twenty-four hours. *All the various tissues* exposed reacted in some way to the radium rays, the reaction of the adenoid tissue and bone marrow being most pronounced. The lymphocytes vanished almost entirely from the blood of the exposed animals and also the polynuclear leucocytes. Next in order of susceptibility comes the epithelium. The epithelial cells are completely destroyed, as a rule, but when certain substances are interposed the cells are *stimulated to redoubled proliferation.*

106 Ein weiterer Beitrag zur Lehre von den Gynatresien. Fromme.
107 Spontaneous Correction of Position of Head with Face Presentation.—Ueber spontane Haltungskorrektur des Kopfes bei Gesichtslage. H. Friolet.
108 *Ergebnisse der abdominalen Radikaloperation des *Gebärmutterscheidenkrebses* mittels Laparotomia hypogastrica (for utero-vaginal cancer). A. Mackenrodt.

96. **Biologic Theory of Eclampsia.**—Labhardt analyzes the relations between the biologic theory of eclampsia and the pathologic anatomic findings and the general principles of biology and pathology. Also the connection between the biologic theory and the clinical manifestations of the affection, and reviews the experiments that have served to sustain the biologic theory. His comment on the whole is that the theory conflicts with what is known and lacks proof to sustain it, *while all the evidence is antagonistic.* The placenta and fetus are not foreign bodies to the maternal organism, and the absorption of their tissue, he declares, does not injure the kidney and *can not be the cause of eclampsia.*

102. **Conservative Treatment of Myoma of Uterus.**—Pincus describes the technic of steam or superheated-air cauterization of the uterus as he has evolved and perfected it, and reviews the *indications for its use.* This method of conservative treatment of uterine lesions has been previously described in these columns.

108. **Results of Abdominal Laparotomy for Uterovaginal Cancer.**—Mackenrodt reports 90 per cent. operability; 19 per cent. mortality; 69 per cent. cures, and recurrence in 12 per cent. of his clinical cases. The frequent discovery of metastases in the parametrium in patients who seemed to be in the incipient stages has compelled him to believe the hypogastric the only safe route. He describes his technic and gives the particulars of his operative intervention in a number of cases.

110. **Tuberculosis in Reptiles.**—Bertarelli succeeded in inoculating the lizard with tuberculosis from human sputa. The lesions were not very extensive in the reptile and the bacilli seemed to become attenuated by their passage through its body, but not sufficiently so to confer vaccinating properties in further inoculation of guinea-pigs. Human bacilli multiplied in amazing numbers after subcutaneous injection into the lizard, but they evidently behaved to a certain extent like saprophytes, adapting themselves to their new host. The reptiles of *the tropics frequently exhibit lesions similar to those found in* this lizard, but they have never been noted before in the reptiles of Italy. Bertarelli suggests that tropical reptiles may prove promising subjects for experimental research in the endeavor to obtain an effectual vaccine against tuberculosis in man.

Address

MODERN PROBLEMS OF METABOLISM.*

PROF. CARL VON NOORDEN.
FRANKFURT-A-MAIN, GERMANY.

Your president has conferred on me a great honor in asking me to deliver one of the opening lectures of the new Harvey Medical Society of this city.

It is your aim that from this well-established center waves of scientific stimulation for research work may arise and reach not only the circles of the professional workers of this city, but even those of the whole country. At this moment, when a society, promoted under such favorable auspices, opens its career by a course of lectures, I think it is opportune, not only to recount the results of investigations already completed, but principally to consider those problems which still await solution.

I am perfectly aware that in doing so I must renounce giving to my hearers the harmonious impression, which a well-worked scheme calls forth; for I am to touch manifold subjects and points of view which stand wide apart and in no organic relation to each other.

Even in confining myself to a very small sphere of the problems of metabolism, a complete and exhaustive representation of such will be impossible. Only a small selection can be made, and even this will savor of arbitrariness.

I may touch, perhaps, on several subjects which to you appear quite unimportant, and, on the other hand, I may omit many points which are of recognized importance. I expressly remark, therefore, that I shall mostly confine myself to questions which enter into my own program for future investigations on the problems of metabolism. If, as a result of my communications, you gain the impression that details of the problems are thrown together by arbitrariness or by chance of selection, I hope that, on the other hand, the personal factor will be the joining link for compensating such disadvantages.

A short retrospect of the history of several problems of metabolism may form a useful preface. All the first investigations, decades ago, were directed toward the recognition of the quality of the chemical changes in the body. The substances, which resulted from the breaking up of the tissues of the body and of the ingested food, were the earliest to be demonstrated. The end-products of animal metabolism were determined. The most important rules were discovered, concerning the production of CO_2, urea, uric acid, kreatinin, indican and hippuric acid, etc. Among the normal end-products, many substances were found which appeared only under certain conditions, and were regarded as characteristic for particular diseases. As examples of such substances I may mention sugar, the various types of albumins, peptone, leucin, tyrosin, lactic acid, cystin, etc. Following this period, in which the names of Wöhler and von Liebig stand out prominently, came the second era, viz., that of pointing out the quantitative changes of metabolism. First introduced by Bischoff, the work in this branch of investigation was carried on and thoroughly established by Carl von Voit and von Pettenkofer and their pupils. Originally confined to the physiologic circumstances in animals and men, this "quantitative study of metabolism" has since obtained new triumphs in its application to clinical medicine and to the study of pathologic processes. It is scarcely twenty years since these investigations commenced, and already, both in the physiologic and in the clinical laboratory, these quantitative estimations are being placed in the background, while attention is being directed to the newer field of the intermediary processes of metabolism. The finest and best work of late years relates to these questions. Hence to-day the investigations on metabolism approach again in character to those of the first period; but what then appeared impossible is now being attacked from all sides. Then one had to be satisfied with a knowledge of the end-products only; to-day one endeavors, through the prominent discoveries in chemistry, to make clear the intermediate stages, through which the metabolites pass to their final conditions. An infinite number of new questions is thus presented by the recent advance in physiologic and pathologic chemistry.

A number of important questions, which are of interest to the physiologist and pathologist alike, however, were left unsolved during the earlier periods of quantitative estimations, and it is only now that—thanks to the better technic of recent times—exact measuring methods are available for their investigation.

First of all, there is the question of the metabolism of energy. Since the time of Voit and Rubner it has been customary to express and to measure body "energy" in terms of calories. In part through the relation of the body weight to the necessary intake of food, and in part from the amount of oxygen consumed and of CO_2 expired, certain average figures have been determined. When an adult man is in a condition of complete muscular rest, from 22 to 24 calories per kilo of body weight are necessary during each twenty-four hours; with usual light work, from 32 to 36 calories are required. The daily food must have these calorific values if the weight of the body shall neither increase nor diminish. With the increase of muscular work, the amount of energy consumed increases in certain proportions, and these latter have been sufficiently ascertained. We know also that children require a relatively high, and old people a relatively low, exchange of energy.

Still, all these are only average numbers and they require the further support of numerous careful and exact observations. Even the most trustworthy figures, obtained by the use of methods, of whose accuracy there is not the slightest shadow of doubt, showed that under exactly the same conditions a difference of from 20 to 25 per cent. arose between single individuals; this can only depend on the so-called individual factors. In future, however, this difference may not be slurred over by the use of the mystic word "individuality"; we must endeavor to make clear the reasons for the rise above the average in oxidative processes in one person, and the fall below the average in another. Such information would provide us with a clear—I might even say a mathematical—insight into the condition which we now designate by the term "individuality."

---

* Lecture read before the Harvey Medical Society, New York, October 14, 1905, in the Academy of Medicine.

An important by-question which arises in regard to the physiology of nutrition, is the problem of the influence exerted on the consumption of energy by the respective constituents of the food.

Certain experiments which Max Rubner and Ed. Pflueger have carried out on animals, tend to show that when the food contains an excessive quantity of proteids the energy-exchange rises considerably above the average. The energy production appeared to rise higher than was necessary for the muscular work done and for the maintenance of the body warmth. These results remind one of the old theory known by the name of "Luxus-consumption," if even it does not entirely compass it. They are too few and insufficient to revive the old hypothesis, which we have long known to be erroneous. As, however, one of the bases of the new science of nutrition is touched by it, the point should be thoroughly cleared up by new and better experiments on human subjects. If the excess of proteid intake really exerts a marked influence on the oxidative processes of the human organism, then we must change many of our views and explain differently a number of former experiments in metabolism. Up to now we trust that not the kind and the amount of food but only the internal and external bodily work rules the extent of the oxidation. The question is not a theoretical one only. Recently manifold endeavors have been made to shake the old standard numbers for the albumin intake of healthy men settled by the school of Voit for these endeavors, which originated from the supporters of vegetarianism, it would be water on their mill if it were proved, that large amounts of albumin raised the consumption of energy to an unseemly, that is to say, to an unnecessary and prodigal, extent. The theory of vegetarianism would also receive a specially strong support were it possible to confirm the oftspoken assertion that the prodigal expenditure of energy only follows an excessive intake of animal albumins and does not result from a similar quantity of vegetable albumins. A few experiments we made lately turned against the theories of Rubner and Pflueger.

Of greatest interest and importance are, of course, those alterations of the exchanges of energy which occur in various diseased conditions. Single and occasional former investigations excluded, we first commenced only about ten or fifteen years ago to busy ourselves with these matters. One single important fact is thoroughly established, viz.: The increase of the energy exchange which follows the administration of thyroid gland substance. This observation, which was made in my clinic by my former assistant, Prof. A. Magnus-Levy was suggested by the practical experiences of Yorke-Davies and Leichtenstern on the influence of thyroid gland tablets on obesity. Later, Magnus-Levy discovered a similar increase in the transformation of energy in exophthalmic goiter and a decrease in myxedema. But these are the only diseases in which, up to now, spontaneous changes in the output of energy are known to occur. Thus the studies—I might call them preliminary—which have hitherto been made on the extent of the processes of oxidation and the amount of nutriment necessary in diseased conditions, afford sufficient reason for the use of our improved methods in further investigations in this field. Many of these problems are of great practical importance for bedside treatment. Next, there is the old question of how great the metabolism energy is in people who are run down by chronic disease or by insufficient nourishment. Do these persons require the same amount of food as do healthy individuals, reckoned per kilo of body weight, or do their bodies diminish the extent of exchange on some self-regulated plan? It is certain that the albumin metabolism is diminished. It has even been asserted that the total production of energy also is diminished, but on this we are as yet without definite proof. My preliminary observations point to the contrary, but the question has not yet been investigated with scientific exactitude. The extremely painstaking and brilliant work of Neumann in Kiel, and of Chittenden in America, which has demonstrated the surprising extent to which the food of an adult man may be diminished without affecting the capacity for work and without altering the nitrogenous equilibrium of the body, leaves untouched this particular question.

Obesity is quite the contrary. For a very long time it has been asserted that there are two forms of obesity. One type is said to result from an excessive intake of food or from insufficient muscular exercise; the other is said to arise from an endogenous retardation of metabolic exchanges. The question is of great theoretical interest, but, as every one must admit, it is also of marked practical therapeutic importance. Since I first approached the matter, some twelve years ago, by investigations on the respiratory exchanges, the question has been constantly discussed. Some differences exist between the results of clinical observation and of laboratory experiments. Clinical reports indicate the occurrence of cases in which the obesity is due only to abnormal lowering of the oxidation, that is, to a diseased state of the protoplasm. Scientifically exact experiments, however, have failed to discover such relations. The results of some work done in the clinic at Basel seemed to point to abnormal low oxidative changes during muscular work and during the digestive processes of obese persons, but they must be discounted by the fact that the methods of estimation employed were not free from objections; correct deductions from them are therefore impossible. I am convinced, however, that with the advent of more satisfactory methods the views of the practitioners will be confirmed by laboratory experiments.

Since the earliest days of investigations on metabolism, the question as to the energy exchanges in fever has received attention. That the albumin exchanges are increased is quite certain; toxic influences are the reason. But why does the patient waste during the periods of fever? Why does he also lose so much of his body fat? As a matter of fact, in every case of long-continued fever, we observe an enormous loss of weight, even if we endeavor to avoid this loss by the administration of rich and nutritious foods. Does the cause lie in the fact that in spite of all our care an individual can not ingest the normal average calories of the food, since the digestive organs during fever are unable to take in or to digest the necessary amount? Or do the oxidative processes in the fever periods rise markedly above the normal? If this is the case, the food requirements of the fever patient will not be satisfied by ordinary quantities; the amount of food sufficient for a healthy individual would not prevent the patient wasting during the stages of fever. The practitioner of earlier times did not doubt that fever was always accompanied by a substantial increase in all the processes of oxidation. The exact investigations on metabolic changes which have been made during the last decades do not, however, confirm these ideas. These consist, in particular, of the works of Senator and some investigations by F. Kraus and by the pupils of Zuntz. If we thoroughly and critically read through these works, we find that they are full of contradictions and by no means permit of any final conclusions being made. The technic of to-day promises, however, a satisfactory and objection-free solution of this old problem. Still, the working out of the matter is naturally dependent on clinical material, and, unfortunately, the majority of hospitals to-day are not equipped with the necessary apparatus.

Among other diseases, in which the energy exchanges should be further investigated, I may mention diabetes mellitus. In slight cases, the relations are simple and undisputed. Such cases do not exert any influence on the energy exchanges.. For a long time, however, it has been supposed—and lately the assertion has been revived on many sides—that in severe cases of diabetes the production of energy, and consequently the food requirements, are distinctly diminished. It has been calculated that in these patients the daily energy needs are satisfied with from 18 to 20 calories per kilo of body weight, while the healthy person requires from 34 to 36 calories under parallel conditions. The question is of great practical importance, because a clear conception would be of real assistance to us in the difficult dietetic treatment of diabetes mellitus. I do not allow the just-mentioned figures, concerning the diminished production of energy in severe cases of diabetes, to be quite correct; and I am of the opinion that the few previous exact observations on the production of CO_2 and the consumption of oxygen, are quite sufficient to prove this. Anyone who possesses a large respiratory apparatus, can definitely settle the entire question in a few days.

We leave now those questions which are intimately connected with the transformation of energy, and turn to another very interesting and important problem, relating to the metabolism of albumin. Earlier experiments on animals and recent investigations on human subjects have taught us that an excessive amount of food compels a retention of nitrogenous substances in the body. The usual nitrogenous equilibrium is disturbed; a smaller quantity of nitrogen appears in the excreta than was present in the food. This retention of nitrogen may be attained by the administration of large amounts of albumin, but much more thoroughly and surely by a simultaneous excess of fat or especially of carbohydrates. The albumin-sparing properties of the two latter substances, of course, are well known. The ultimate effect of such overnutrition is always an increase in the total quantity of fat. We apply this knowledge therapeutically in our "feeding cure," etc. But regarding the nitrogen there was until a short time ago the opinion that in spite of such an excessive nutrition, the nitrogen retention was only slight in quantity and short in duration—at least so far as well-nourished adults are concerned. It was taught that the body always endeavors to maintain a nitrogenous equilibrium so that, in the case of over nutrition while the excess storing of fat may continue for a long time, a similar storing of proteids is soon stopped. In certain cases, however, the storing of body proteids seemed to be both extensive and long continued, as for instance, during the period of body growth, or after chronic exhaustive diseases, or after periods of lowered nutrition—it is always during the new growth of tissues. The occurrence of considerable nitrogen retention has recently been noted, apart from the conditions just mentioned. In a case of my own, I found that in two months not less than 370 grams of nitrogen were retained. Expressed in terms of meat this is more than 11 kg. of flesh. Is this retained nitrogen really built up into pure albumins and protoplasmic substance? Our general knowledge tends to indicate otherwise. We know that excessive feeding produces obese, but never athletic, individuals. *A priori,* it is very improbable that the nitrogen retained during excessive nutrition indicates the formation of pure albumins or a new formation of tissue substance. Perhaps the nitrogen only exists in the form of nitrogen-containing fragments of the large molecules of albumin, which are held for a time and are then cast off at a later period. In favor of this supposition there is the fact, that when the period of excessive nutrition is stopped, it is usual for an enormous quantity of nitrogen to appear in the urine.

The exact form in which the nitrogen is retained within the body is still, however, entirely unknown. It is, nevertheless, an important question, because a knowledge of it would throw light on the changes which the molecules of albumin undergo in the body.

This problem leads us by easy paths to the consideration of the intermediate stages of metabolism, which is the special field of modern physiologic chemistry.

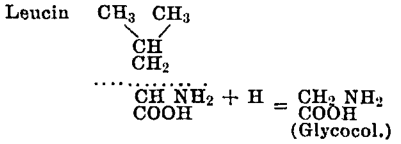
Naturally, most questions of the "intermediary" metabolism concern themselves directly or indirectly with the fate of the albumin molecules; with their disintegration as well as with their synthesis. It seems that the synthesis of albumin in the body may originate from much simpler molecules than we could conceive of until lately. By intense and long-continued tryptic digestion of albumin, the latter has been broken up until the solution no longer yields the biuret reaction. In spite of this, the administration of the products of such digestion to animals, served for the substitution of pure albumins and for the maintenance of nitrogenous equilibrium.

In close theoretical relation to this brilliant and important experiment of Otto Loewi stand those considerations, which are bound up with the discovery of erepsin in the walls of the alimentary canal. This ferment splits up the albumoses and peptones into simpler substances and, in particular, splits off the amino-acids. Hence, it has been assumed, that this action represents the regular arrangement of processes, that the organism normally lives on the amino-acid mixtures, and that from these basal substances are formed the albumins which ultimately circulate in the blood stream. Such a sweeping conclusion, however, is a little too previous, for it has been shown recently that erepsin occurs in all the organs of the body and thus is not specific for the alimentary tract. The ferment, which *in vitro* is able to split up the albumoses when acting in the intestine may, synthetically, form albmumoses from amino-acids. Such reversibility of ferments is already ~~k~~nown. These considerations appear to indicate, therefore, that the real function of the intestinal mucosa is not to break up the albumoses into amino-acids, but, on the contrary, to build up albumoses and similar substances out of the amino-acids, which pass into the intestinal wall from the lumen. The question is certainly an available one for further experimental investigations. First of all, the living and surviving intestinal mucosa must be allowed to act on a mixture of amino-acids. This experiment has not yet been made. It is one, of course, which is very important for our ideas concerning the assimilation of albuminous substances. If the investigation yielded positive results, there would be a remarkable analogy between this process and that of the synthesis of fat by the intestinal cells. Concerning the fate of fats, we know (1) that a fat-splitting ferment (lipase) is present in the intestinal wall; (2) that by the aid of this ferment there also occurs in the intestinal wall a synthesis of fat from fatty acids and glycerin; (3) that *in vitro* this synthetic process can be reproduced by the aid of lipase. For these brilliant and important investigations we are indebted to your own countryman, Dr. Loewenhardt.

These questions are of great significance in practical dietetics, since they bring into greater application the until now almost entirely neglected amino-acids. In particular, rectal feeding would receive a new impetus. Among the amino-acids there are many substances which are less irritable to the mucosa of the large intestine and are more easily absorbed than the usually prescribed albumoses and peptones. We have already commenced investigations on this point.

Associated with the amino-acids, which represent the chief nitrogen-containing group of the albumin molecules, are many other questions, only a few of which can be touched on here. The chief of my clinical laboratory, Dr. G. Embden, has lately made an investigation on the amino-acids under physiologic and pathologic conditions. What I have to say on this point is due chiefly to the important theoretical and analytical work of Dr. Embden.

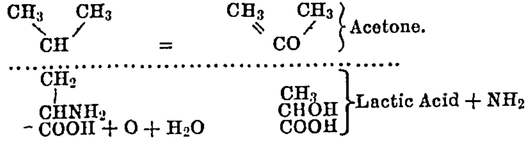
First, I have to mention that glycocol probably can be split off from all the amino-acids, the chains of the higher constituted amino-acids being broken up between α and β C-atom.



This process, it would appear, plays a great part in the organism. Recent investigations in my laboratory have shown that glycocol is normally present in all urines, and in such quantities as to approach up to 1 per cent. of the total nitrogen output. This well-grounded observation is striking, because we have for a long time known that glycocol introduced into the stomach is very easily assimilated and reappears as urea in the urine. The formation of glycocol within the body must be very large, if the kidney is able to catch and to eliminate some portion of it. This production of glycocol from the higher amino-acids may also explain how it is that the body always has glycocol at its disposal for coupling or combination purposes. I recall to mind the instances of hippuric and glycocolic acids. Further experiments must be performed, however, in order to determine whether or not the administration of large quantities of the higher amino-acids is followed by the appearance of a supernormal amount of glycocol in the urine.

If the formation of glycocol from the higher amino-acids takes place in the manner which our preliminary investigations suggest as being probable, then a new light will be shed on the question of the formation of sugar from albumins. Since it has been established that higher amino-acids, such as alanin, form a definite source for sugar (G. Embden and H. Salomon), G. Embden, working in my laboratory, has shown that after the removal of the pancreas in dogs, sugar is formed from glycocol equally as it is from alanin and other higher amino-acids. Glycocol seems to be one of the most prolific sources of sugar that we know of. This fact, taken in connection with the previously mentioned conditons of glycocol formation out of other amino-acids, explains at one stroke the question of sugar formation from albumins, and effectively removes those objections which have been heard during the most recent years.

Glycocol, however, does not seem to be the only amino-acid from which sugar can be rapidly formed. Our attention has also been directed specially to leucin, for the reason that of all the amino-acids leucin occurs most largely in the majority of the proteids of food. We are quite certain that lactic acid can be produced from alanin, and that in fact this procedure takes place within the body. A similar possibility obtains for the formation of lactic acid out of leucin. Theoretically, on the addition of water and oxidation, leucin breaks up into acetone and lactic acid, while at the same time amides are split off. Attention only just recently has been drawn to how often this process occurs in the chemistry of animal tissues and how important it is. In this case the chain of C-atoms is broken between the β and γ atom. You see, there are different possibilities of disintegration of the same molecule.



In confirmation of these theoretical possibilities, we have just proved that the "surviving" liver always excretes some acetone into perfused blood, and that the amount of acetone considerably increases when leucin is added to the inflowing blood. At the same time, as we have determined with certainty the formation of lactic acid from leucin, we are met with a new problem, associated with the as yet unknown changes during the passage of carbohydrates through the body. We certainly know the end-products of carbohydrate disintegration—carbonic acid and water—but in regard to the intermediary metabolism of carbohydrates and the manner in which those end-products are produced we are still in the realm of theories. Entirely disconnected facts are alone our guides. One of the earliest theories related to the formation of lactic acid from carbohydrates; but until now no satisfactory proof of this was given to us, at all events so far as muscular tissues are concerned. Many physiologists consider the lactic-acid formation in muscle to be due to postmortem changes. The modern technics, which have advanced perfusion methods to a remarkable extent, will make possible a definite solution of the problem; until now, it is only solved so far as the liver is concerned. In my laboratory, Embden and Almaggia have thoroughly demonstrated that lactic acid ensues in fact from disintegration of carbohydrates by the liver. This result arises from the action of a ferment and, as all our experiences with organic ferments indicate that the action of these ferments is reversible, so this procedure may also take place in the reverse way. As a matter of fact, we know that very often the administration of lactic acid to individuals affected with severe diabetes, and more especially to dogs after removal of the pancreas, is followed by an increase in the glycosuria. We also consider lactic acid as a rich source of glycogen. These few available facts lead to the following hypothesis:

A part of the sugar which is broken up in the muscle circulates in the blood as lactic acid; the lactic acid passes to the liver and is there rebuilt up to carbohydrate and eventually reaches anew the muscles in the form of sugar. With this conception of the intermediary stages and circulation of the carbohydrates in the form of lactic acid, some well-known facts are in full agreement. After extirpation of the liver, sugar disappears from the blood stream and lactic acid makes its appearance. Another remarkable fact may also be explained on this hypothesis. When the pancreas is removed from birds, glycosuria does not result. In these animals, lactic acid is not bound to be regenerated into sugar, but with the addition of ammonia, it can form uric acid. If this view be a correct one, then the uric acid of the bird is partly a derivative of sugar. I advance this theory, of course, only in the form of an hypothesis; it has, in any case, the advantage of promoting further investigations on the intermediary stages of carbohydrate metabolism and of providing a new aim and a definite proposition for further proof.

I have already mentioned that, theoretically, acetone may be produced from leucin, and that we have been able to demonstrate this procedure by experiments on animals. This result is very remarkable, since the opinions of to-day designate the fatty acids alone, and the lower fatty acids in particular, as the source of the acetone bodies, and because until now we have always accepted the oxybutyric and diacetic acids as the necessary precedents to acetone. This latter view thus requires correction, although our experiments in no way show that in the formation of acetone leucin plays an important figure in respect to quantity. At all events, it indicates that the acetone question can not yet enter into a condition of rest. Also the problems of the formation of acetone from fat and the hindrance to the production of acetone through the simultaneous oxidation of carbohydrate, are still sufficiently enigmatical and can not be solved until we know much more about the intermediary disintegration of fats and of carbohydrates than we do up to this day.

With this I wish to conclude my survey of modern problems of metabolism. As I stated at the commencement of the lecture, it has been necessary to roam over a large amount of ground and to consider subjects that were but slightly related to each other. You will observe that to-day we are busying ourselves in a much more intimate manner with the details of metabolic processes than in not very remote periods was deemed either necessary or possible. Already the little that has been mentioned here is more than the working powers of one single man can master; but on all sides we see new young energy pouring into this interesting and important branch of medical investigation, in order to harvest this inexhaustible field. We greet them with joy and with satisfaction. The results will not be long in coming.

We are all convinced that these marked steps into the wonderland of animal metabolism will not only advance the theoretical science, but, as we have always seen, that every advance in physiologic and pathologic chemistry has been followed by improvement of our bedside treatment. The achievements of the dietetic treatment of diseases have gone hand in hand with the advances in theoretical investigations. If we compare the progress in dietetics that has been made during the last decade with the wonderful successes of the surgeon, the medical clinician no longer need feel either shame or envy. In the same period a vast amount of work has been done by the internist in regard to therapeutic matters. The close relations which have been maintained between the progress in clinical bedside treatment on the one hand and physiologic and pathologic chemistry on the other, has been very fruitful indeed, and still fruitful will remain.

Great problems still await solution and rich outside help is necessary thereto. With confident expectation, medical science looks to this country, in which in recent times numerous ardent and honest research-loving young workers have entered into the service of problems of metabolism, and in which the riches and the munificence of its inhabitants more than elsewhere have provided that external aid which has made more easy the prosecution of great and far-reaching investigations. I close with the prophetic words of our Goethe:

> Amerika, Du hast es besser
> Als unser Continent der Alte.

COCCIDIOIDAL GRANULOMA.[*]

W. OPHÜLS, M.D.

SAN FRANCISCO.

We have in California a peculiar form of oidiomycosis of which, so far, no cases have been described in people who had not been in our state, except the very first case of this form of infection which was observed by Wernicke[1] in Buenos Ayres and later more accurately described by Posadas. The first case in California was reported by Dr. E. Rixford[2] of San Francisco to the San Francisco Medico-Chirurgical Society, March 4, 1894. Another similar case under the care of Drs. Thorne[3] and Robinson was seen by him[4] the same year. Later Dr. Rixford,[5] in conjunction with Dr. Gilchrist of the Johns Hopkins Hospital Medical School, gave a more complete description of these two cases and of the parasite.

This description established fully the morphology of the parasite in the tissues and the nature of the lesions which it produces. At that time, however, the organism was looked on as a protozoon, on account of failure to obtain growths, and on account of a certain resemblance to the coccidia named *Coccidiodides immitis pyogenes resp.*, the idea being that on account of some morphologic differences the parasites in the two cases might not be the same. This view of the animal nature of the parasite proved to be erroneous in the course of the examination[6] of a new case of this disease which occurred in 1900, when it became apparent that the parasite could be cultivated and developed in the cultures in the form of a mould-like growth. It probably belongs to the oidia. I have therefore proposed the name *Oidium coccidioides.*

The lesions as well as the parasite of coccidioidal granuloma show certain resemblances to the tissue changes and organisms found in blastomycetic dermatitis as described by Gilchrist, Stokes and Gilchrist, Wells, Hessler, Hyde, Hektoen, Montgomery and others. There is this difference, however, that whereas in blastomycetic dermatitis the primary focus of infection always is the skin and the disease remains localized in that organ, with the exception of one case reported by Walker and Montgomery,[7] in which a generalization of the process took place; such generalization of the disease is the rule in coccidioidal granuloma and the primary focus of infection is just as frequently to be found in the interior of the body as in the skin. Typical cutaneous lesions are often missing entirely. The parasite in coccidioidal granuloma differs from the various fungi described in blastomycetic dermatitis first by the absence of budding during its development in the tissues, second by its multiplication by endosporulation, third by certain differences in its growth on artificial culture media. Still the resemblances between lesions and parasites in blastomycetic dermatitis and those in coccidioidal granuloma seem close enough to my idea to classify them together, perhaps after Ricketts' suggestion, as oidiomycoses. It must be acknowledged, though, that there is this difficulty in the way of accepting Ricketts' nomenclature, namely, that under the term oidiomycoses should be included all diseases produced by oidia, whereas Ricketts attempts to limit the term to what is commonly known as blastomycetic dermatitis, a few cases of more general infection with yeast fungi and infections with *Oidium coccidioides.* On the other hand, the term blastomycosis would hardly include all the fungi which cause these troubles. Many of them are very much more complicated in their modes of development than ordinary blastomyces. In this dilemma about names I believe we should look rather to the professional botanist than to the medical worker for a decision whether these organisms should be properly classified as blastomycetes or as oidia. Certain is this, that we have here a class of diseases usually with the anatomic characters of granulomata frequently localized in the skin but also occurring in other organs which is caused by a variety of lower fungi, some resembling more blastomycetes, others more oidia.

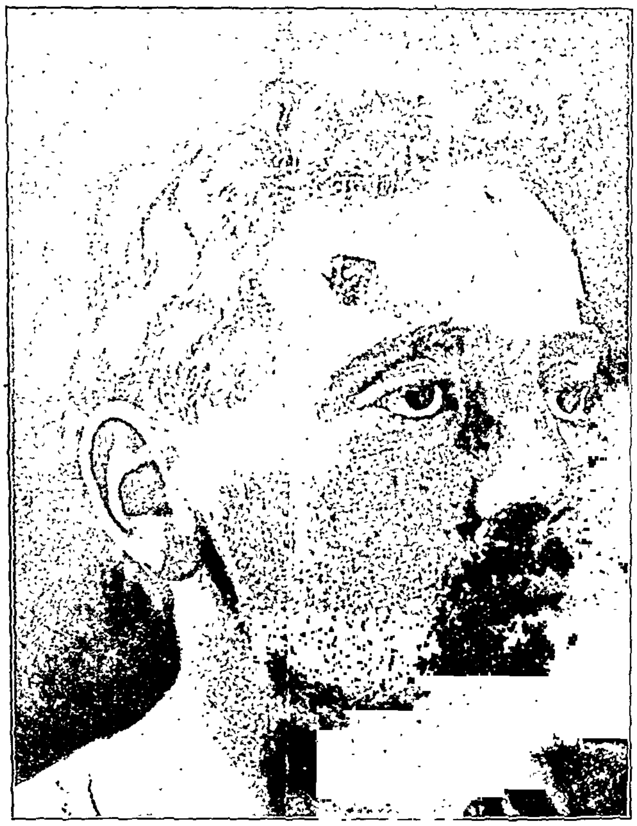

Fig. 1.—Face lesions in Case 4. From article by Montgomery (British Journal of Dermatology, xii, 1900).

There are now on record 10 cases of coccidioidal granuloma, to which I can add three new cases, making 13 in all.[8] Unfortunately, the records of the three new cases are not complete.

One of these is the case of a young canner, C. M., 19 years of age, who came to the City and County Hospital at San Francisco Sept. 23, 1901. Before entering the hospital he had irregular attacks of fever with violent chills for four weeks. In the hospital he developed the symptoms of a severe, unusually chronic meningitis and died Dec. 17, 3 months after entering. The necropsy showed an old calcified caseous spot in one of the peribronchial lymph glands on the left side, one old miliary tubercle in the left kidney, a chronic irregular caseous process in both adrenals, a basilar meningitis with many tubercles in the Sylvian fissures and a very extensive chronic inflammation of the pia mater of the spinal cord which in places was 3 to 4 mm. thick and full of tubercles and submiliary abscesses. The spinal cord showed a marked softening especially in the periphery underneath the thickened pia mater. He also had a terminal bronchopneumonia and beginning cystitis and pyelitis in consequence of a paralysis of the bladder which developed toward the last and necessitated catheterization. At the time the case was regarded as an ordinary case of tuberculosis. No attempts were therefore made to obtain cultures. Several years later only, adult and sporulating forms of *Oidium coccidioides* were discovered in sections from the meninges. One of the most remarkable features of this case is that tubercle bacilli and no other parasites were found in the adrenals, whereas no tubercle bacilli, but many oidia could be demonstrated in the meninges.

The second case was one observed at the German Hospital in San Francisco in Dr. Weil's service, to whom I am much indebted for allowing me to make use of it here. The patient was an old man, born in Germany in 1842. When 16 years old he had an enlargement of the glands of the neck with extensive suppuration, which after considerable time healed with the formation of large scars. He came to America in 1874, lived in New York, San Francisco, Oakland and Sacramento. He was employed most of the time as a baker or as a mill hand. In Sacramento he was overseer of a large market. He never lived in the San Joaquin Valley. Toward the end of 1903 a large cold abscess developed on the left side of his chest which was opened in March, 1904. Two ribs were resected. The wound remained open ever since. Later soft fluctuating swellings developed on both sides of his neck. In June, 1904, Dr. Weil curetted the open sinus and removed some diseased bone. Microscopic examination of the granulation tissue showed miliary and submiliary chronic abscesses, some with giant cells in their walls and in these abscesses the parasites; there were many sporulating forms. Some time afterward the patient was discharged, apparently cured.

In the third case, Chinese, W. D., at the City and County

[7] "Further Report of a Previously Recorded Case of Blastomycosis of the Skin; Systemic Infection with Blastomyces, Death, Autopsy," The Journal A. M. A., 1902, vol. xxxviii, 867.

[8] At the end of the paper is a short synopsis of the cases already published and a more detailed account of the new cases. The numbers in the text refer to the numbers given to the cases in that place.

Hospital, the external condyle of the right humerus was removed in June, 1905, on account of caries involving the elbow joint. Microscopic examination of the specimen showed fibrous thickening and cellular infiltration of the periosteum and the adjoining muscle. There was extensive destruction of the bone with formation of tubercle-like nodules with large giant cells of the Langhans' type. In other places there were submiliary chronic abscesses. One section shows a large area of diffuse caseation. In the latter were many large full grown parasites. In one of the submiliary abscesses was a typical sporulating form. The patient died with symptoms of a chronic pulmonary trouble with sputum in which no tubercle bacilli could be found. He also had a paralysis of both legs. Unfortunately in this case also no necropsy could be made.

If we look over the cases so far reported in order to obtain a clinical and anatomic picture of the disease, we find that on account of the great variety of lesions produced by the parasite and the great variety of organs affected, it is very difficult to make any generalizations. The clinical symptoms in these cases, of course, depend entirely on the localization of the disease in the different organs of the body and the extent to which these organs have been involved in the process. So far no typical clinical picture can be given, but in some cases there is a striking resemblance to tuberculosis. In regard to the anatomic changes, one can say that the disease belongs to the infectious granulomata resembling tuberculosis, although at times differing from it in certain respects. As in all infectious granulomata the manifestations of the disease are very manifold, the most characteristic, of course, being nodules consisting of granulation-tissue at various stages of development, but in addition to such lesions and mixed with them we find suppurative processes usually of a chronic character which in exceptional instances may be quite acute, however. The infection with *Oidium coccidioides* therefore produces either submiliary, miliary or larger nodules, which resemble tubercles very closely. These nodules may caseate. Later the caseous material may liquefy and cavities containing pus-like material may be produced in this way. Or, in other cases, there may be suppuration from the beginning, sometimes of a rather acute type, but usually more chronic in character, leading to the formation of miliary or larger, sometimes very large (size of an infant's head) chronic abscesses or chronic ulcers. The lesions are nearly always progressive, with marked tendency to dissemination by the lymph and blood current, still sometimes they may heal eventually. In this tendency to rather rapid spreading in the same organ and from one organ to another, and in the more suppurative character of the lesions the disease at times resembles glanders more closely than tuberculosis, although it has been clinically most often confounded with the latter.

Six of the 12 cases which have been reported more accurately had peculiar skin lesions. The appearance of these differed considerably in the different cases. Sometimes they were composed of large tubers with more or less ulceration, recalling the clinical picture of mycosis fungoides. This was observed in Cases 1 and 4.[8] The lesions in the latter case are shown in Fig. 1. In Cases 2 and 8 the nodules in the skin were much smaller and the trouble had the appearance of a hypertrophic lupus, as shown in Fig. 2. Again in Case 3, the lesions were more ulcerative in character, there was less tumefaction at the edges of the ulcers and instead of more or less solid nodules, submilliary abscesses were largely encountered (Fig. 3). The trouble in these cases usually started in some exposed part of the skin and extended from there discontinuously more or less all over the body. In one of my cases, a Japanese, there was only one ulcer on the foot, of the appearance of a simple chronic ulcer without tumefaction, nodules or miliary abscesses at the margins. The ulcer was covered with a thick brown scab.

These cutaneous lesions seem to have been the primary seat of infection in 4 of the 6 cases. In Cases 4 and 8 this is a little doubtful, because in both of them there were symptoms of internal disease before the cutaneous manifestations developed. Case 4 apparently is an example of primary pulmonary infection, of which there are two more instances among my own cases. In Case 5 the first clinical symptom was a pleurisy on the left side, and at the necropsy the lungs were found extensively involved. In the other, Case 6, there were old scars at both apices, from which the process probably had started. Case 7 also probably has to be regarded as a primary pulmonary infection; otherwise the source of infection would be entirely obscure in this instance, in spite of careful anatomic investigation. In the other cases there was no chance for investigation sufficient to obtain any clue in regard to the mode of infection.

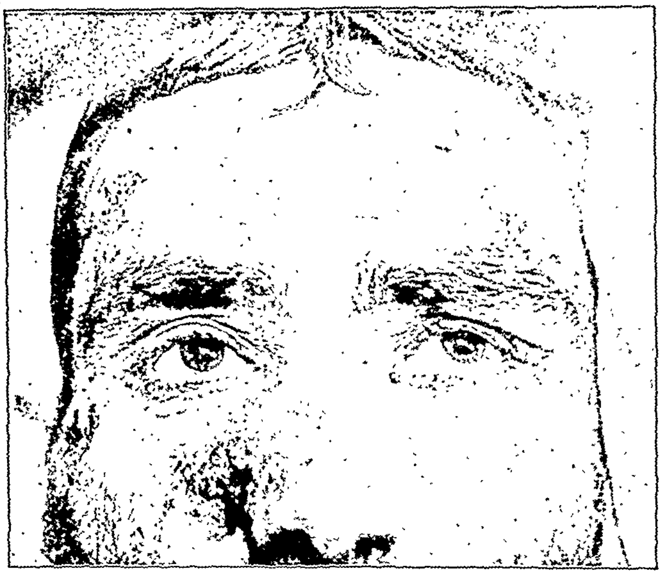

Fig. 3.—Face lesions from Case 3, second case of Rixford and Gilchrist (Johns Hopkins Hospital Reports, I).

In the lungs a variety of conditions have been observed. In Case 6 nothing was left in the lungs except small scars at the apices, whereas in other cases the lesions were rapidly progressive and very destructive. Case 5, which is a typical example, showed irregular nodular consolidations, with extensive caseation and abscess formation, many disseminated miliary nodules and small abscesses, several large abscesses, one extending into mediastinum and another into the diaphragm. There was an empyema on the left side. The early involvement of the pleura and the extension of intrapulmonary abscesses into adjoining viscera (mediastinum, diaphragm, soft tissues of the lower neck, etc.) seem to be rather characteristic of the disease.

If the lungs are infected secondarily by the blood current, the result, as a rule, seems to be the formation of innumerable miliary nodules, very much like those observed in acute disseminated miliary tuberculosis. These also occur in such instances in spleen, liver and kidneys and may or may not develop in these organs into small chronic abscesses.

The lymph glands are affected early and extensively. They usually show enlargement, caseations and suppuration

In its predilection for certain organs the disease is rather similar to tuberculosis. The adrenals are frequently diseased (mentioned in Cases 2, 7, 8). In all three cases the lesion consisted in an extensive caseation of these organs. Basilar meningitis, resembling tubercular meningitis very closely, was observed in Cases 6 and 7. In Case 6 the lesions were rather acute, like ordinary tubercular meningitis, whereas in Case 7 the process was very much more chronic, lasting for over three months.

Disease of the bones was noticed in Cases 2, 5, 10, 11, 12. The trouble was often multiple and had the appearance of a chronic suppurative periostitis and osteomyelitis, with caseation. Here, again, in some instances particularly, the resemblance to tubercular caries was quite marked.

In one case only (Case 2) the internal genitalia were affected. There was a chronic caseation and suppuration of prostate, seminal vesicles, both epididymides and testes. This observation is interesting on account of the invariably occurring chronic suppurative periorchitis in guinea-pigs after intraperitoneal injection.

The histology of the lesions is remarkable on account of the close resemblance of some of the lesions to those produced by the tubercle bacillus, showing that in tuberculosis, just as in all other diseases, the reaction of the tissues to the virus is not specific or in any way pathognomonic. In coccidiodal granuloma we also observe histologically interesting transitional stages between small chronic abscesses and tubercle-like nodules, which, however, although more rarely, may also be found in cases of tuberculosis. Figure 4 shows, in one section "typical" tubercles, with giant cells of the Langhans' type and submiliary abscesses surrounded by thick layers of epithelioid cells. In Figure 5 several of the "tubercle"-like nodules are shown with the high power. In Figure 6 we see a similar nodule with a central abscess cavity filled with polymorphonuclear leucocytes, and in Figure 7 a chronic abscess* surrounded by epithelioid cells. On one side in the layer of epithelioid cells there is a small giant cell. Figure 8 is taken from the edge of a larger tubercle and shows typical caseation.

Examples of more acute lesions are given in Figs. 9 and 10. In Fig. 9 one sees an irregular accumulation of cells, largely polymorphonuclear leucocytes, in the meninges with beginning necrosis in places, and Fig. 10 illustrates the thick wall of one of the larger chronic progressive abscesses in Case 2. There is a thick layer of granulation tissue, the superficial layers of which are necrotic. In the granulation tissue there are many parasites; around some of them small abscesses are noticeable.

The *Oidium coccidioides* occurs in the tissues in the form of spherical bodies that grow to about 30 microns in diameter, consisting of an irregularly staining protoplasmic body and a double-contoured capsule which in the larger forms is thick and often covered on the outside with prickles or even long spines (Fig. 11). Different from the parasites in blastomycetic dermatitis, these spherical forms do not multiply by budding, but by endosporulation, as shown in Fig. 12. The formation of spores is preceded by a division of the protoplasm into 2, 4, 8, 16, etc., parts. The spores may number 100 and more. They are liberated by a bursting of the capsule and grow out directly either outside or often still within the old capsules into young spherical parasites. If many sporulating forms are present, the process is usually more acute and more suppurative in character. The number of the parasites in the lesions varies a good deal. Usually they are numerous enough to be easily found, at other times several sections have to be carefully studied before they are noticed. In pus they are most easily found when a drop of fresh pus is spread between coverslip and slide and looked at with the low power.

When one of the adult parasites is placed in a suitable medium it grows out into long septate hyphæ in the manner shown in Fig. 13, iv and v, developing in course of time into a mouldlike growth (Fig. 15). It is probable that the spores also may be the starting point of such growth (Fig. 13, vi). It is not always easy to obtain the first growth, because not all parasites give rise to the formation of hyphæ, and they do so only when they are free, entirely separated from the tissues. A drop of pus is the best material for starting a culture. Solid tissue containing parasites must be carefully teased or ground in a sterilized mortar before a growth can be obtained.

The fungus grows well on all media in the incubator and more slowly at room temperature. Fig. 14, iv, shows the mycelium of a fresh culture which consists of cylindrical septate branching hyphæ. After varying intervals, sometimes a month or more, spores develop in the ends of the hyphæ (Figs. 13, i, and 14, i). These spores are of interest, because from them, after introduction into the tissues, the spherical forms develop in the manner shown in Fig. 13, vii, by direct enlargement. As long as the culture does not contain any spores it is not infectious. Spherical forms with endosporulation are never observed in ordinary cultures, nor are mycelia ever found in the tissues. Wolbach, however, succeeded in developing the spherical forms with endosporulation outside the tissues in collodion sacs placed in the peritoneal cavity of animals.

The spores which form on artificial media can also be the starting point of a new growth on new media (Fig. 13, iii). The spores are first biconcave on both sides with sharp edges, later they may take all sorts of irregular forms (Fig. 14, iii). In old cultures I have found a few times yeast-like growths like the one shown in Fig. 14, ii.

Experiments have shown that dogs, rabbits and guinea-pigs are very susceptible to infection with *Oidium coccidioides*. The cutaneous lesions have been reproduced in dogs. Intraperitoneal injection is followed by chronic inflammation of the omentum with formation of nodules and abscesses, the formation of nodules on the peritoneum in liver and spleen and sometimes in pleura and lungs. In male guinea-pigs and rabbits, as has already been mentioned, a chronic suppurative periochitis develops after this form of infection.

After intravenous injection the chief lesions are encountered in the lungs in the form of innumerable miliary nodules; most other organs, however, are usually affected similarly and sometimes bone lesions occur. Fig. 16 gives an illustration of the lesions in the omentum of a guinea-pig. The microphotograph, which is taken with a very low power, shows numerous small abscesses in a mass of cicatricial tissue. In Fig. 17 a more tubercle-like lesion from the lower side of the diaphragm of an animal is represented.

So far it has not been possible to trace the source of the infection in any of the human cases. As mentioned

---

* Editor's Note: A chronic *miliary* abscess. The word *biliary*, under the cut, is a typographical error.

before, the disease seems to be almost limited to California. Most cases have come from San Joaquin Valley, but some have been observed in people who have never been in that part of the country. There has not been an epidemic outbreak in any place as far as is known. The cases have been found at considerable intervals in San Francisco in people coming from the country and had no apparent relation to one another. Several of the patients have been working as day laborers on the railroads, but not all of them, by any means. From what we know from the cultivation experiments it would seem quite possible that the oidium occurred in nature and caused infection occasionally only. Since animals are susceptible to it, it has been suggested that the trouble might be primarily an animal disease and only occasionally transmitted to human beings, but so far it has not been possible to adduce any evidence in support of this theory. I am fairly convinced that the cases are more frequent than would appear now. The resemblance of the disease to tuberculosis is so great clinically and anatomically that the true nature of the cases is recognized only when a careful microscopic examination is made of the diseased tissues or the pus from the lesions.

SYNOPSIS OF CASES.

Case 1.—Case of Posadas and Wernicke (*Centralbl. für Bact.* 1892. *Revue de Chirurgie*, March, 1900, etc.) First symptom: appearance of bluish red tumor of size of lentil on right cheek, later large ulcerating nodules resembling mycosis fungoides appeared in various parts of the skin. Secondary involvement of regionary lymph glands. The disease lasted seven years. At autopsy disseminated nodular lesions were found in the internal organs.

Case 2.—First case of Rixford and Gilchrist (*Johns Hopkins Hospital Reports*, I). Observed 1894. Male, 40 years old. First manifestation: sores on forehead and back of neck, later, disseminated cutaneous lesions resembling hypertrophic lupus. Nine years after first symptoms involvement of regionary lymph glands, death one year later. Lesions found in internal organs at autopsy: chronic abscesses, disseminated nodules, old scars and irregular areas of consolidation in lungs; chronic nodular pleurisy, nodules in diaphragm, circumscribed chronic nodular peritonitis underneath diaphragm and in pelvis, caseation and suppuration in peribronchial and retroperitoneal lymph glands, disseminated nodules in spleen, caseation of both adrenals, caseation and suppuration of prostate, seminal vesicles, both epididymides and testes, chronic suppurative and caseous osteomyelitis of middle of left tibia and head of metacarpal bone of left index finger.

Case 3.—Second case of Rixford and Gilchrist (*Johns Hopkins Hospital Reports*, 1). Observed 1894. Male, 33 years old. First symptom: two small pimples on forehead developing into chronic ulcers, later progressive disseminated ulcerative lesions of skin, early involvement of regionary lymph glands. Night sweats, remittent fever. Duration of disease 3 months. No necropsy.

Case 4.—Case of Montgomery (*British Journal of Dermatology*, XII, 1900). Male, 21 years old. First symptoms: cough ten months before death. Two months before death appearance of large nodules resembling mycosis fungoides in skin over right eye which ulcerated, later widely disseminated cutaneous lesions. High remittent fever with night sweats. Secondary involvement of regionary lymph glands, rapid increase in pulmonary symptoms. Finding in internal organs at autopsy: large abscess in upper part of right lung extending underneath clavicle into soft tissues of neck. Several smaller abscesses and consolidated areas in right lung. Large abscess in right lobe of liver.

Case 5.—Case of Moffitt and Ophüls (*Phil. Med. Jour.*, 1900, *Jour. of Exp. Med.* 1905, VI). A. L., male, 19 years old. First symptom: chill followed by pleurisy: later multiple arthritis, osteomyelitis of frontal bone. Slight chills and profuse sweating. Duration of disease: three months. Lesions found at autopsy. Irregular nodular consolidation with caseation and abscess formation in lungs, also disseminated miliary nodules, and larger abscesses extending into mediastinum and diaphragm. Empyema on left side, caseation and suppuration of retroperitoneal lymph glands, disseminated miliary nodules in liver, disseminated nodules and abscesses in kidneys and spleen, purulent periostitis and osteomyelitis of frontal bone, both tibias. Suppurative inflammation of both knees, right shoulder, both elbows and both wrists. Cultures obtained.

Case 6.—G. B. (*Jour. of Exp. Med.*, 1905, VI.), old man. No clinical history. Lesions found at autopsy: Old partly healed lesions at apices, chronic nodular pericarditis, disseminated nodules in spleen and kidneys, basilar nodular meningitis.

Case 7 (New case).—C. M., canner, 19 years, came to City and County Hospital, Sept, 23, 1901, had been in San Joaquin Valley for 12 days the month before, stopping at Bakersfield and Fresno. Before entering the hospital he had irregular attacks of fever with violent chills for four weeks. On entering he had high remittent fever, no plasmodia could be found, leucocytes normal, much headache, marked rigidity of neck, tenderness of cervical vertebræ, constipation. Kernig's symptom was present but not very marked. At intervals the patient was in stupor or at times delirious. December 5, unequal pupils, complete paralysis of left abducens. December 6, paralysis of bladder. December 9, bed sores. He died December 17. At autopsy an old calcified caseous spot was found in one of the peribronchial lymph glands on left side, one old miliary tubercle in the left kidney, chronic caseation in adrenals (tubercle bacilli found in sections, no oidia). Basilar meningitis with many disseminated nodules in Sylvian fissures, very chronic inflammation of pia mater of spinal cord with thickening to 3-4 mm. in diameter. In thickened pia many miliary nodules and abscesses. Marked softening of cord. Terminal bronchopneumonia and beginning cystitis and pyelitis. The case was first regarded as an infection with tubercle bacilli. Later adult and sporulating forms were found in the meninges, no tubercle bacilli could be demonstrated in them.

Case 8.—Case of Montgomery, Ryfkogel and Morrow (*Jour. of Cut. Dis.*, Jan., 1905). Findings at autopsy: Disseminated cutaneous lesions resembling hypertrophic lupus. No old lesions in lungs but many disseminated miliary nodules which were also present in spleen, liver and kidneys. Chronic caseation of adrenals. Cultures obtained.

Case 9.—Japanese (*Jour. of Exp. Med.*, VI., 1905). Chronic simple ulcer of foot, caseation and suppuration of inguinal lymph glands and one of cervical lymph glands. This patient was later treated at the City and County Hospital in Dr. Huntington's service for a large abscess of the anterior abdominal wall which extended into the pelvis. The abscess was opened and drained. The patient discharged improved. It has been impossible to trace him since he left the hospital.

Case 10.—Case of Gardner and Halton. An unusual infection in the bones of the foot. San Francisco County Medical Society, November, 1904. *Cal. State Journal*, 1904. Old man who worked on the railroad in the San Joaquin Valley. In 1900 he had an accident to right foot, followed by an abscess on the dorsum of foot. The abscess was opened and healed. Foot remained swollen and tender. In 1904 abscess formed over fourth metatarsal bone. It was freely opened and considerable necrotic bone and pale granulation removed. Curettings show caseation and formation of tubercle-like nodules. Many adult and some sporulating parasites. Amputation of foot. The patient is otherwise apparently in perfect health. Cultures obtained.

Case 11 (New case).—D., patient at German Hospital, service of Dr. Weil. Male, German, born 1842. When 16 years old, while still in Germany he had an enlargement of the glands of neck with suppuration which after considerable time healed with formation of large scars. He came to America in 1874, lived in New York until 1877, then came to San Francisco, where he stayed until 1880. Then he moved to Oakland remaining there until 1897, when he moved to Sacramento. He has never lived in the San Joaquin Valley. He worked as baker, millhand and in Sacramento as overseer of large market, where he had to handle poultry, rabbits, etc.

Does not remember having seen many diseased animals. Toward the end of 1903 a large cold abscess developed on left side of his chest which was opened in March, 1904. Two ribs were resected. The wound remained open ever since. Large soft fluctuating swellings developed on both sides of his neck. Dr. Weil curetted the open sinus and removed some diseased bone. Microscopic examination of the granulation tissue showed miliary and submiliary chronic abscesses, some with giant cells in their wall. In these abscesses the parasites were found. Many sporulating forms. Cultures obtained.

CASE 12 (New case).—Chinese patient, of City and County Hospital, June, 1905. The external condyle of the right humerus was resected for caries which involved the joint. Microscopic examination of the specimen showed fibrous thickening and cellular infiltration of the periosteum and adjoining muscle; extensive destruction of bone with formation of granulation tissue full of tubercle-like nodules with large giant cells of Langhans' type. In other places there were submiliary abscesses. One section showed a large area of diffuse caseation. In the latter many large adult parasites and some empty shells. In one of abscesses a typical sporulating form. The patient suffered from a chronic pulmonary trouble with much purulent expectoration, no tubercle bacilli could be found. There was also a paraplegia of both legs. The patient spoke Chinese only, so no history could be obtained. He died within a short time, but unfortunately no autopsy was obtained.

CASE 13.—Parasites described by Wolbach, *Journal of Medical Research*, XIII., 1904.

DISCUSSION.

DR. H. A. L. RYFKOGEL, San Francisco, said that Dr. Ophüls has seen 12 cases in such a short time because he was looking for them. It may be demonstrated later that in California and in certain other parts of the universe the disease is fairly prevalent. Dr. Ryfkogel mentioned a case in which he was able to make the bacteriologic diagnosis. The clinical diagnosis had been made previously by Dr. Montgomery. For a number of years the case had been diagnosed as one of tuberculous disease of the skin. At first, Dr. Ryfkogel was not able to find the parasites in the cultures, and Dr. Flexner and Dr. Opie also tried to get them, but failed. Finally, Dr. Ryfkogel succeeded in finding them, as he realized after studying the sections made by Dr. Montgomery that the parasites were in the dense fibrous layers of the skin, and that none was on the surface. He found that in this case it was impossible to produce the disease experimentally by subcutaneous injections. Dr. Ophüls had the same experience with the cases he studied. It was easy to inoculate animals intraperitoneally. Of 100 animals inoculated, all developed caseous abscesses in all parts of the body, but only two out of the 100 developed pulmonary symptoms. These two died of miliary coccidioidal tuberculosis of the lungs, none of these abscesses being present. The original case suddenly developed symptoms that led to a diagnosis of pneumonia, and from this complication the patient died. There were no bone lesions, but the skin lesions were very extensive. There was enlargement of the suprarenal capsules with caseation, the size being that of a large orange. There was an acute miliary tuberculosis of the lungs, due to the fungus, not to the tubercle bacillus.

THE OCULAR ORIGIN OF "MIGRAINE."[*]

GEORGE M. GOULD, M.D.
PHILADELPHIA.

If one looks into the etymology of the words megrim, hemicrania, the megrims, or migraine, he finds that the words are in origin identical; moreover, the complex, nowadays designated by these silly and meaningless terms, is made up of a hundred symptoms having nothing to do with half-headedness; and most of them are of vastly more importance than half-headedness, or even than pain on or in one side of the head. If one glances at the literature of the history of "migraine," he finds that scarcely any two authors understand the same thing by the word. If one consults present-day text-books and monographs on the subject, there is the same confusion and misunderstanding. If one should ask any score or hundred of physicians for a definition and clinical picture of the disease, there would be the same astonishing indefiniteness and contradiction in the answers. If one should ask as to the etiology, there would be the most numerous, amusing and disorderly array of a hundred causes. If one seeks to learn what organs are affected, the answers, if any are hazarded, would be found equally wide of the mark. The affection in all its forms and types is tremendously common, and yet about it exists the most amazing ignorance and opposition of view. As to therapeutics—well, professional powerlessness, utter and absolute, is confessed. Up to now our impotence has been as complete as our nescience.

Unwary authors sometimes speak of a "typical case of migraine," without explaining what they mean by the term. Text-books, dictionaries and professors seek, indeed, to indoctrinate the student with ideas of the typicalness of various diseases, even of "migraine," but woe to the practitioner who tries to find a case in actual life. In a broad way, and serving as a suggestive and useful distinction, however loose, all diseases may, in truth, be divided into those which usually run a typical course and those which are rarely or never typical. The more uniform and similar the course of any disease in different patients the more certainly it may be ascribed to a single, simple cause, acting on a single organ or set of organs. Such diseases are those which are highly infectious, such as yellow fever, typhoid fever, smallpox, etc. Even here, of course, the seed is not all and the soil of no importance, for the typical picture always has some slight or great variations in the outworkings of large numbers. Of the atypical diseases, migraine is, by all odds, the leader. Any detailed description is at once false and impossible. No case-history is like that of another. This is, first, because its cause, eyestrain, is of a thousand different kinds and intensities, two cases never being alike; and, secondly, because vision is bound up in some way with almost every physiologic function and necessity; it is united with every nerve-center, every bodily and psychic activity. Thus the infinitely varied morbid cause or seed is planted in an infinitely varied soil. So important is the eye itself to life and to the organism that the morbid reflex is usually not allowed to wreck itself on the eyeball, but starts at first to morbidize the cerebral organs. Hence, headache is, of all the symptoms of so-called migraine, the most constant and frequent. The low degrees of ametropia, especially astigmatism, never to be quite overcome, but the attempt to do so never to be avoided, harm the general system worse; the high defects harm the eye the most.

In a rough way we may say that the symptoms most bespoken in this disease may be grouped in six classes:

1. Periodicity, or alternation of attack and freedom from attack; but no two cases showing the same law either as to length of time between attacks, or during which the attacks last.
2. Scotoma scintillans, if occurring, always preceding the headache; half of the time not followed by headache or other symptom.

---

[*] Read at the meeting of the American Academy of Ophthalmology and Otolaryngology held in Buffalo, N. Y., Sept. 14-16, 1905.

3. Headache, insided, outsided, one-sided, both-sided, front-sided, back-sided, top-sided, bottom-sided, of a hundred different kinds, intensities, and characteristics, and ascribed to a thousand different causes.

4. Nausea, retching or vomiting, of all possible irregularities, regularities, intensities, lengths, present in a minority of cases; the vomiting, when occurring, clearing up the crisis in a majority of cases, and followed by a re-establishment of temporary health. The nausea, patients say, is worse than the vomiting.

5. Psychic and nervous symptoms, such as dejection, often proceeding to profound depression and even to suicidal tendencies, together with nameless and indescribable sufferings, each person's descriptions differing from another's, but all agreeing in seeming exaggeration, with possible insomnia, "hysteria," "neurasthenia," "nervous break-down," etc.

6. Physical symptoms accompanying the attacks, or following them, or replacing them during the intervals between, such as anesthesias and hyperesthesias of many kinds, extents and intensities, paralyses, functional cardiac diseases, aphonia, influenzas and "colds," digestive disturbances and dyspepsias, skin diseases, "rheumatisms" and localized pains, spinal or shoulder pains, neuralgias, and many other symptoms.

With one or more of these classes of symptoms absent, with two or more classes mixed in a limitless number of combinations and degrees, it is evident that there can be no "typical case," and the attempt to set the confines and describe the symptoms implicated is highly absurd. All late authors lessen the difficulty, first by a vagueness, which is a crying *confessio ignorantiæ,* and then they cut out of the list Classes 5 and 6, i. e., the psychic and physical concurrents and consequents; usually, also, they do not know what to do with the pestiferous scotoma scintillans. As the periodicity is never alike, is, indeed, if present, infinitely variable, this also has to be ignored. This leaves simply headache, combined with nausea or vomiting, which, of course, should simply be called "sick headache." But never did two patients have the same kind and degree and continuousness either of headache or of stomach rebellion, and we are landed in a farcical *reductio ad absurdum.* But the solemn neurologists do not know it, and they keep crying that any described case is not migraine, not "typical," doesn't fit in their boxes, is hysteria, nonsense, a contemptible oculist's whimsy. Some of these gentlemen assume the air of Mark Twain's jumping frog, make great exertions, but they never get "forrarder" by one inch. They fling a bombastic word, "psychosis," "dementia præcox," "hysteria," "neurasthenia," etc., at the poor patient, order her to the sanitarium or to Europe, prescribe bromids, placebos, or the rest-cure; they then prepare the next edition of their text-book in which ignorance of nervous diseases vies with therapeutic nihilism. If the oculist says he knows a cause and a cure for many cases, Dr. Dana will inform him that "the only real mental affection connected with eye strain is the symptom-complex with grandiose ideas on the part of ophthalmologists." Dr. Fisher will also add:

> The oculist is not expected to have such a knowledge of these diseases, either pathologically or clinically, as would make his opinion of any special value, and, therefore, his statements and opinions should be taken only in such a sense as from his limited horizon of observation a partial understanding of these conditions renders possible.

Shakespeare and Molière in collaboration could not do justice to the antics of some of our modern neurologists, neither to some of our defunct commercial medical journals, whose ghosts are sometimes draped so realistically by their publishers that one would almost think them really medical and as much alive as the famous Mr. Partridge and his almanac. The *Medical Brief,* the *Medical Mirror,* the *Philadelphia Medical Journal,* the *New York Medical Journal,* the *Medical News*—how from their graves they hate and belabor the oculists! The *News,* even after its death, was heard to gibber that at least 20 per cent. of our citizens have gastric ulcer which the surgeon should excise at once. Think of 16,000,000 American citizens being ordered to be gastrotomized in the next 24 hours! But that, of course, is better than spectacles!

When one carefully observes this attitude of mind it becomes evident that these opposers and ridiculers are most anxious to find that the sufferers from migraine, epilepsy, neurasthenia, hysteria, melancholia, indigestion and headache are, thank God, incurable. Their fury in ridiculing the refractionist, their blindness to his truth, their immoral misrepresenting and misreporting him, their editorial malevolence, are indicative of "much." If they had a spark of true scientific spirit, they would be glad to examine a theory and the facts supporting it which might bring some light into their darkness as to the origin of "migraine." If they had the least therapeutic zeal they would like to cure some of their patients of diseases they have all admitted incurable. If they had the least pity in their hearts of human suffering they would grasp at even a slight possibility of lessening the agonies of millions of their fellow-citizens. But of some neurologists and editors of defunct commerciomedical journals one scarcely expects humanity or medicine. What, then, shall be said of oculists who join them? Nothing, except to wonder what kind of refraction they are doing, not to have seen every day their patients cured of these diseases by the glasses ordered. Were there a scintilla of the true investigator's spirit in their minds they would themselves put on their own noses the glasses that we say cure these patients, and test the theory. In a week they would have all the migraine needed, at least, to reduce even them to silence. I will guarantee to produce by this laudable human vivisection experiment, in the skeptics and cynics, any desired degree of "neurosis," "migraine," "neurasthenia," "hysteria," "melancholia," "dementia præcox," "degeneration," "nervous break-down," "neurotic predisposition," "katatonic state," "major psychosis," "melancholia of involution," "psychical tonus or contracture," "forme fruste," "manic depressive insanity," "confusional psychosis," "pseudoneurasthenia," "mysophobia," "topoalgia," "neurasthenical syndrome," and the rest. And all with a pair of 0.75 D. cylinders! The committee appointed must be composed of non-presbyopes and made up equally of neurologists, the editors of defunct commercial medical journals, and ultraconservative "opthalmologic surgeons."

There is hardly a case of severe eyestrain reflex that, viewed in the life-history, does not show a persisting morbid cause acting on the organism, as it were, from without. Balzac said that when he did not have head misery he had digestive wretchedness, and *vice versa.* In the majority we see this cause attacking one organ after another, upsetting the normal functions of the mind, brain, stomach, liver, heart, lungs, skin or eliminative organs, and all according to the kinds of ametropia present and the amount of work demanded of the eyes. Eye-rest at once gives relief. When presbyopia is added, some one organ is often incapable of further normal function, and there is an end of life. Of what use are the empty words, "neurosis," "neurotic inheritance," "psychosis," etc., in such cases? Their users are tragical jokers both with science and humanity. Every good refractionist knows that the little fallacy underlying their bad logic is that, in the past, accurate refraction has not been secured for the sufferers, or that, rarely, prevention has been ignored until chronicity has made cure impossible. Not even a pair of spectacles can raise the dead.

It all comes back to the test of facts. I have epitomized a few random notes I happen to have of cases reported by good physicians of the cure of migraine by glasses. I could doubtless have gathered hundreds more if time had permitted.

For instance, about *seventy years ago Piorry caught* a glimpse of the true relation of the eye and *megrim;* he thought that "monophthalmalgia," or "iralgia," affections of the peripheral nerves of the eye were the cause of migraine.

To Dr. William Thomson, of Philadelphia and of America, is undoubtedly due the credit of first demonstrating in a general way the causal relation of eyestrain to these nervous and migrainous disorders. This part of the history I have elsewhere indicated and epitomized. In 1876 Mitchell, in reporting Thomson's cases, might have honored himself and the profession by seeing that migraine is due to eyestrain. He came near it; but finally and clearly he balked, and neurology again failed to realize its possibilities.

About the same time Dr. R. Brudenell Carter, in his treatise on "Diseases of the Eye," 1875, reports the case of a patient with palpitation of the heart,[1] headache and sickness (Anglice, nausea and probably vomiting), attributed to disease of the brain; he was first sent to Australia without betterment; he gave up business and a proposed marriage, his "prospects in life blighted." A pair of glasses cured him of all symptoms.

The first physician to lay down clearly the proposition that sick headache is due to eyestrain was Dr. G. C. Savage.[2] To him, therefore, all honor. He was an American. He announced that he had discovered the "real cause" of sick headache to be hypermetropic astigmatism, and that its successful treatment consisted in the use of proper glasses. Savage made a minor and natural mistake in limiting the cause of migraine to "hyperopia and astigmatism, either alone or combined," but he did not commit the egregious blunder of rushing to tenotomy; he did not even speak of heterophoria. The brilliancy of the discovery and the bravery in announcing it, on Savage's part, almost, if not entirely, counterbalance his subsequent silence, mysterious and insoluble, of twenty-five years, on this revolutionizing subject. Savage describes the circumstances that led up to his discovery and the rationale of the method of the cure of sick headache by glasses. His own is the first case reported. [It is, indeed, a pity that every physician in the world is not a sufferer from the disease. He could, of course, be cured with ease, and the generation-long shame of ignoring and opposing a truth of enormous importance would end as suddenly as yellow fever in Cuba.] Savage's mother had had as violent sick headaches as her son, but age, of course, had cured her. Atropin was as effective in our colleague's case, and glasses made the cure *permanent. His sister,* too, was *cured in the same way, and also his preceptor,* Dr. Clark. Savage comments wisely on the false views of the authors of text-books of medical practice on the subject and on their utter ignoring of the matter; he adds:

> Although sick headache is as common as it is dreadful, Bartholow and other writers on the practice of medicine have not said a word about it.

In 1883 Lauder Brunton, not a crank oculist, wrote[3] as follows:

> But frontal headache is not the only one which may arise from abnormal conditions of the eyes, for megrim or sick headache is very frequently associated with, and probably dependent on, inequality of the eyes, either in the way of astigmatism, myopia or hypermetropia.

In 1883 Lauder Brunton, not a crank oculist, wrote[3] fact that "correction of the eyes by cylindrical glasses relieved not only the headache, but also the intermediate dyspepsia, insomnia and irritability of temper liable to occur in patients between the attacks of megrim."

In 1886 Dr. Ambrose L. Ranney[5] said that "the symptoms of sick headache are reflex in character, to a large extent, and are due primarily in almost every case to some optical defect."

In 1887 Dr. George T. Stevens issued his noteworthy book, "Functional Nervous Diseases," etc., in which he made what I judge is the beginning of a huge mistake in saying that "unlike the ordinary forms of headache migraine does not so frequently yield to simple measures of adopting glasses to correct refractive errors." The common inaccuracy at that time in correcting errors of refraction may, at least partially, excuse this error. It is noteworthy that *of five cases reported in this book the* first four were reported as cured without tenotomy. It is, I think, unfortunate that the operation was not also omitted in the thousands of cases since.

The next, and of all hitherto the most scientific, demonstration of the ocular origin of "migraine" was made by Dr. G. Martin.[6] He reports in all 352 cases, with details, of the ametropia, etc. (mostly low degrees of astigmatism, of course)—a truly noble work. One's patriotism suggests the wish that he had been an American.

In 1889 George M. Gould[7] reported the cure of cases of chorea, severe dyspepsia, cardiac palpitation, sick headache, sexual disorders, etc., due to eyestrain, and in January, 1890, others of similar nature,[8] such as stammering, paralysis, anesthesia, chorea, gastric disorders, aphonia, etc. In August, 1890, he wrote,[9] "Sick headache, there can be little doubt, is very often, if not generally, due to eye strain, etc. In 1891, in reporting[10] on 833 cases of headaches, this man found 73 cases clearly to be classed as sick headache, and he then said, "Ninety or ninety-five per cent. of cases are due to the eyes." He now says 99 per cent.

Dr. George E. de Schweinitz, in an address before the Medical and Chirurgical Faculty of Maryland, April 26, 1900, said:

> It is unquestionably true that fully 75 per cent. of ocular disorders depend on anomalies of the refraction, accommodation and motility of the eyes. Correction of such faults is followed by the greatest good to the eye and to the general organism in which the strain has been interpreted by symp-

---

[1] It is remarkable how often eyestrain is found to produce tachycardia or other functional cardiac symptoms. I think that exophthalmic goiter is usually, if not always, due to the same cause.

toms not necessarily suggestive of their origin. When one comes to *think* about them, these symptoms stretch out into an extraordinary train, but we have ceased to wonder, and as a matter of course *investigate or cause* to be investigated the eyes whenever searching for the etiology of headache of all kinds, vertigo, nausea, pseudo and habit chorea, neurasthenia and other disease phenomena of similar manifestation. We *have learned that many* so-called gastric troubles, tachycardia, flatulent and other types of dyspepsia, indigestions, night terrors, especially as they occur in children, may have a like origin, and we have found out that pains strangely and persistently situated in the nape of the neck, between and under the shoulder blades, at the end of the spine and deep in the mastoid may owe their origin to the same cause. These facts are widely, I think I may say universally, known, although, curiously enough, many of the most important of them find no place in the most used text-books on general medicine.

Dr. James Hinshelwood[11] writes:

> Such headaches due to errors of refraction may be extremely severe, *sometimes accompanied by vomiting,* and may even interrupt the patient's work (sic!). They resemble an attack of megrim, but they differ from true megrim in their bilateral distribution, and in the absence of any of the higher visual phenomena, such as fortification figures or defects in the visual fields.

One is glad to have the testimony, all the more convincing because of the writer's residence in an etymologic and clinical antiquity.

Dr. S. W. S. Toms[12] reports a case of "typical" sick headache in a man of 26 existing since he was a schoolboy, with vomiting, prostration, fainting attacks, facial pallor, small, thready pulse of high tension and frequency, the attacks lasting from one to three days. There was numbness of the extremities, scotoma scintillans, etc. For eight months after Dr. Toms ordered glasses the man had no attack; then there was one, due to bent spectacle frame; later he broke his frame and there was another attack. Other cases similar in nature are reported by Dr. Toms.

Dr. Peter A. Callan,[13] of New York, writes of migraine: "I have frequently found that correcting 0.25 D. of astigmatism has given complete relief." He cites one case of "a lady, ten years ago, who had suffered long and frequently from migraine, who was cured by wearing glasses." He concludes, from an extended experience of years, with hundreds of cases, that he is "forced to regard eyestrain as the cause in over 75 per cent. of all the cases of functional headache and migraine." This was in 1891; in a personal letter Dr. Callan says that years before this he "claimed that eyestrain is the cause of migraine, and acted accordingly.

Sydney Stephenson[14] reports a case of headache, four times a week, usually lasting all day, and "now and then terminating in vomiting. In fourteen months after glasses had been prescribed there had been only a few slight attacks. Another case reported in the same article was that of a medical student with such severe headache and nausea that his parents thought to put him to another occupation. He was entirely cured by glasses. Both these patients had unsymmetric astigmatism. In a second article[15] Mr. Stephenson says "megrim is an affection that in my experience is often connected closely with ocular defects." "This," he adds, "is no new observation."

The following cases are reported by Stephenson:[16]

> Let me quote the following case where the sequence of cause and effect appeared to be singularly free from fallacy: A very intelligent medical friend had suffered slightly from megrim since he was 7 years of age, but as he got older, and especially as he was reading for his professional examinations the bouts had become severer and more frequent. He was affected, in fact, with classical "blind headache." The attacks began with a colored scintillating obscuration of central vision, and as this passed away, as it generally did in five to ten minutes, intense unilateral headache supervened. The attacks were always associated with nausea. They were brought on by (a) indigestion (b) straining the eyes, as with the microscope. There was a family predisposition to megrim; the patient's mother and sister suffered severely from the affection, and two of his children were also affected. The headache, as a rule, did not last for longer than an hour, but on one occasion it persisted for four days without intermission. General remedies did little, if any, good. At last, at the age of about 39 years, the slight hypermetropic astigmatism (0.5 D.) was corrected with spectacles for constant wear. The result was almost magical. The headaches became fewer in number and milder in character, and this has continued until the present time, some fifteen years after the glasses were prescribed. It may be added that severe headaches can still be induced by attempting to use the eyes without glasses.
>
> In the next case the relief afforded by weak glasses was very prompt and striking: Grace C., aged 22, consulted me in November, 1902. She was a fine, robust-looking country girl, but had always been subject to headaches, which had become worse during the last two years. The pain, which was ushered in by ocular spectra, affected the frontal region, and generally lasted a whole day. It was followed by vomiting. She generally had two or three such headaches during the week. The eyes were stated to ache and to get red after close work. The headaches were definitely induced by reading or working. General medical and dietetic treatment had proved useless. On examination no defect of the external ocular muscles could be found; there was 1 D. of hypermetropia in the right eye and 0.75 D. in the left eye. Spectacles correcting this small amount of long sight were ordered for constant wear. After six weeks' use of glasses Miss C. reported that there had been no return of the headache, and that there was no aching, etc., of the eyes.

Stephenson correctly contends that migraine is not very rare in childhood. He cites the following case:

> I have met with fairly typical attacks in children as young as 6 years. The following case, although occurring in an older child, may be quoted because one or two unusual symptoms were present: George D., aged 10, had suffered from three attacks of megrim, the first in the autumn of 1900. The attacks commence with an alteration in speech and a numbness of the right arm, and are followed by persistent vomiting. There is a strong family history of typical hemicrania, preceded by *hemianopsia,* in the mother and several of her people. The patient, on examination under atropin, was found to be affected with an extremely low grade of hypermetropic astigmatism, and the weakest cylinder of the trial case (+ 0.25 D.), with its axis *horizontal,* was ordered for constant use. In the result, the megrim disappeared completely, and had not returned when the patient was seen a year afterward.

Dr. George H. Thomas,[17] of Minneapolis, says:

> I have come to a settled conviction that . . . among these neuroses [due to eyestrain] I would place in order of frequency neurasthenia (which might include insomnia, irritability, weariness, and mental confusion), nervous dyspepsia, vertigo (including some forms of car sickness and sea sickness), and, finally, migraine. Every oculist has had cases of migraine which have certainly been permanently relieved and sometimes completely cured. I could quote from my records typical cases, etc. Why eye-strain produces in one person headaches, in another blepharitis; in one nervous dyspepsia, and in another general nervous prostration; in one migraine, and in another epilepsy, is still a subject confined to the realm of theoretical speculation, logical and convincing as that might be made to appear. What we do know, however, is that there

is a large amount of clinical evidence, which is growing larger every day, which shows that when certain patients with a great variety of neurotic symptoms are relieved of their eye-strain, in many of them these symptoms also disappear.

Mr. N. Bishop Farman[18] describes his own case of migraine "neurovascular storm," "associated with the visual centers," and caused by incorrect glasses.

Dr. Zimmerman,[19] in his elaborate study, excludes from his table cases of hemicrania without nausea or vomiting, and also, most strangely, twenty-five cases of bilateral headache in which nausea and vomiting appeared. I say "strangely," because the etymology of the word, half-headedness, has long been put aside as having anything significant of "migraine." Dr. Zimmerman then tabulates what he calls his "true migraines"—"9 cases caused by eyes," 8 cases cured by glasses," and "3 cases improved by glasses."

Drs. S. Solis-Cohen and A. A. Eshner, general practitioners of Philadelphia, were the first in any American text-book on medical practice (issued in 1892) to acknowledge frankly that migraine may be due to eyestrain. In 1904 Dr. Cohen[20] has said further:

> The dependence of migraine on eyestrain as an exciting cause in a large number of cases can no longer be denied by the most doubting Thomas. . . . Unquestionably it is a truth of vast significance. Unquestionably physicians have not yet fully realized that significance.

Dr. George F. Libby[21] epitomizes the reports of ten cases suffering from nausea and headache combined, in which "correction of the refractive error gave relief in each case." In three cases with nausea unassociated with headache, relief was obtained in two cases, the third not reporting.

Dr. A. L. Derdiger[22] reports a severe case of chorea of fifteen years' continuance, with migraine symptoms, completely cured by glasses relieving her unsymmetric astigmatism. Another of Dr. Derdiger's patients was a lady, aged 24, with atrocious migraine for five years, the crises occurring once or twice a week. The patient's symptoms would make the neurologist cry hysteria! with a loud voice, and consign her to the rest-cure, or to the bow-wows. I, therefore, must quote her own description of her hypochondriac symptoms:

> I have been a sufferer for years; in one day I have about fifty diseases, my head and stomach especially. I can not eat. If I eat the lightest food, then I have indigestion; so I don't eat at all. I can't sleep, and if I do sleep for a few minutes I have such horrible dreams; I dream I am here, there, and everywhere. If I sleep a little I am always moaning, for pains are all over my body. First my back, I can't stoop, then my chest, all down my sides, my shoulders, my legs; then the pain goes toward my stomach and head, and the pain stops there. I have been to vegetarians and they told me not to eat meat, so I have not eaten meat for years. I have been to Christian scientists, and they have prayed with me, aloud and in silence, and kept it up for a long time, until I lost courage. I have taken all sorts of massage and tried all sorts of remedies for years. I see there is no improvement, but the reverse. I can't even wash a cup.
>
> I have taken treatment from mental scientist and electric doctors, and all kinds of doctors, for a long time, but the pain became so severe that I can't stand on my feet but a few minutes before everything turns black before me. I get dizzy, buzzing in the ears, my sight grows dim, the heart palpitates, my whole body quivers, a cold sweat breaks out all over me, I feel deathly sick to my stomach, the bowels get loose, and the pain becomes so severe in my head and stomach that I am obliged to fall on the bed; sometimes I stay in bed a few hours, other times two or three days. I always thought that I had a complaint in my heart, but the physicians have examined me in private and at the hospital and said my heart was well. Even when I wash myself the pain I have is terrible; sometimes I feel so heavy that I can't move myself, and I also have a burning in my body. This burning kills me altogether, for it leaves me very weak. I have been taking music lessons, but after a half-hour practice I have such pains that even the nails of my fingers ache. After singing awhile the letters become blurred, my voice becomes husky, and the eyelids twitch so that I tremble all over.

With each attack she was forced to go to bed, and intense nausea and vomiting was always present. Three mydriatic testings were required to bring out the unsymmetric astigmatism and anisometropia, the right axis at 105°, the left 90°. She was completely cured by her glasses. Dr. Derdiger's third case was one denominated "classical neurasthenia," also cured by ocular treatment.

Dr. J. Herbert Claiborne[23] says:

> I can cite several cases [of migraine] in young adults, in whom the recurrence of the periodic attack and all the accompanying symptoms have been absolutely prevented by the correction of an ocular defect. . . . I reiterate the statement that I have had a number of cases in my practice in which the recurrence of sick headache has been absolutely prevented by the corrections of refractive errors.

Mr. Simeon Snell[24] says:

> Many instances of this disorder [migraine] in which the classical symptoms are present will be relieved by giving attention to ocular errors. Two medical friends who have been closely associated with me have experienced an almost entire absence of the disorder since their astigmatism was corrected. . . . Vomiting and nausea are also symptoms. . . . It is well known that they are prominent and well-recognized symptoms of some eye diseases. . . . The remedy for the condition met with in these cases is attention to the eyes.

Mr. Snell describes a number of illustrative cases, one of which was of a very severe migraine, cured by glasses.

Dr. Myles Standish, after quoting a number of statements which he characterized as dogmatic and misrepresenting, from reviews in The Journal of the American Medical Association, the *Ophthalmic Review*, the old-time *Medical Record*, the *Medical News*, etc., said before the Boston Society for Medical Improvement, Dec. 5, 1904:

> After having listened to the above extracts, I think you will readily agree with me that it ill behooves the authors of these editorials and book reviews to accuse Dr. Gould of extravagance of statement. . . .
>
> It must have happened to every oculist who has prescribed glasses for patients suffering from migraine that when the patients returned after two or three years they related that they had been entirely relieved until quite recently, and that the return of the migraine and other nervous symptoms made them think that their glasses should be changed. After examination a change usually seems advisable, and they will probably return again two or three years later and repeat that they were immediately relieved by the glasses prescribed and that their symptoms have only again recently returned. Such cases are by no means uncommon. . . .
>
> You will have noticed that in the extracts I read you in reference to migraine great stress is laid on the fact that migraine is often inherited, but, gentlemen, are not eyes inherited? It is very common to find similar refractive errors running through a whole family, and I myself have cognizance of one well-known family in which there were twenty cases of convergent strabismus in three generations.

Dr. Allen Greenwood,[25] of Boston, says of the backward school-child whose objective symptoms are those of eyestrain that "frequently the complaint is of increasing headache so that on arriving home the little sufferer has to be put to bed with what is called sick headache."

Dr. Edwin E. Jack,[26] of Boston, says:

> In just what proportion of cases of migraine the nerve storm is caused or precipitated by ocular strain I do not know, but I have no doubt of the connection in very many, and it would seem to me a grave omission in all such cases not to put the eyes into the best possible condition for work, even when there are no local symptoms. . . . Experience teaches that nausea, dizziness, dyspepsia, "the blues," nervousness and irritability, insomnia, brainfag, neurasthenia and a general inability to take up the burdens of life, may all be influenced, aided or brought about by the ever-present effort of the eyes to overcome an imperfect shape or balance. To one who has seen many times the mental wreck which eyes can cause, such a connection is far from incredible and, indeed, does not seem unusual. It is, of course, hard for many to see this standpoint. The man who reads in a moving, joggling car, with his glasses askew, and has always done so with no hint of discomfort, can not understand why I, many times under similar circumstances and in a very few minutes, have nausea and an upset stomach. This would easily prove to me, even if I were not an oculist, that the eye can affect the stomach, and experience teaches me that it can be a factor in other things as well. It would be easy, I think, to demonstrate some of these symptoms by wearing prisms placed in a certain way, or by the use for a while of cylindrical lenses with wrong axes.

Dr. Edward Payson Morrow[27] says:

> It is fairly well understood that headaches, vertigo, confusion of ideas, nausea, and many allied symptoms, as well as functional disturbances of remote organs, may have their origin in eyestrain.

Dr. Frederick E. Cheney, an oculist of Boston, says in a personal letter:

> As to sick headaches, I certainly expect to cure the greater proportion of them.

The editor of the *St. Paul Medical Journal*[28] says:

> That headache, insomnia, night terrors, nervous dyspepsia, sick headache, migraine, and a host of other similar symptoms result from eyestrain, and are relieved by proper glasses, every physician, and especially every oculist, is well aware.

Dr. S. D. Risley, Philadelphia, has reported cases of the cure of "typical migraine" by means of glasses, and expresses himself as generally agreeing with the thesis.

Dr. W. H. Carmalt, New Haven, asks, "What ophthalmologist has not had the same or similar experiences?"

Dr. A. G. Bennett, Buffalo, "heartily indorses such conclusions."

Dr. W. F. Southard,[29] San Francisco, writes:

> There is no specialist who has kept an accurate record of his cases for a series of years but will bear Dr. Gould out in his conclusions.

After a half-century of personal experience in conscientious refraction work Dr. John Green says:

> To me the central and very significant fact is that the prostrated sufferings, always alleviated by rest from eye work and always recurring with the resumption of studious pursuits, as portrayed in the several biographies from which you have culled, are such as ophthalmic practitioners recognize as dependent, in many persons, on common ocular defects, and as preventable or curable by properly directed optical treatment. . . . It is surely not an extravagant contention that eyes which do not perform their function perfectly in all respects and under all conditions, or whose use is attended or followed either by local disturbances or by headache, nausea, insomnia, or other reflex manifestations, ought, without exception, to be promptly and critically examined. That such examination will very often bring to light a previously unrecognized ocular defect, and so point the way to urgently needed relief through wearing properly chosen and properly adjusted spectacles, needs only to be stated to command assent. The knowledge that relief from headache may come through wearing glasses is becoming more and more widely diffused; but comparatively few physicians have learned, as yet, to recognize the protean forms which reflex disorders of ocular origin may take on, or to estimate at its true value the service which a wise and conscientious ophthalmic specialist may be able to render.
>
> The investigation and treatment of functional disorders dependent on structural imperfections of the visual organs call for the exercise of the minutest care, and often of almost infinite tact and patience. That the essential qualifications are sometimes conspicuously lacking in men eminent for their achievements along other lines is also true. Careless or perfunctory refractive work by an ophthalmic specialist will yield no better results than similarly defective work done by persons of inferior scientific attainments and of vastly less reputation.

At the 1905 meeting of the American Academy of Ophthalmology and Otolaryngology, either publicly or by personal communication, many members expressed themselves as assenting in a general way and in varying degrees to the proposition that "migraine" or sick headache is caused by eyestrain. Dr. Carhart of New York said that when we are able to overcome the total ocular defects we can cure all cases. Dr. Weeks said that perhaps 75 per cent. of cases are curable by ocular treatment, but that the claim of a higher percentage was not justified. Dr. Baker of Cleveland said, "Let us be honest and frank. We all cure such cases every day."

Mr. C. Ernest Pronger,[24] Harrogate, England, considers extensively the cases of headache with nausea, retching or vomiting, and reports many cases of typical migraine—if the word may be used—or sick headache; many had been treated by other physicians for years, with no relief until proper glasses were ordered. It is noteworthy how often the attacks recurred when the glasses were not worn, or were broken, until the patients learned the lesson. Mr. Pronger suggests that suicide is frequently due to eyestrain, the melancholia, nervous debility and insomnia being so frequently associated with the symptoms.

Brav[30] reports three cases of persistent vomiting in school children, associated with headache, dizziness, convulsive movements, etc., completely cured by correction of astigmatism, and he concludes that in school children vomiting is very often caused by astigmatic errors of refraction.

Dr. A. Ernest Gallant of New York (personal communication) thus writes:

> I most emphatically know that, in women at least, not less than 25 or 30 per cent. of sick headache depends on eyestrain, and in my own practice in the neighborhood of 300 have been cured by wearing glasses when fitted by competent men. I learned to look for this condition after reading your first paper in the *Medical News* some years ago, and have thus relieved many whom others have failed to cure. This fact can not be too strongly impressed on the minds of students, and must be hammered into the graduates of former years, etc.

Another general physician, Dr. H. Jarrett, Camden, N. J., says:

> It has been my personal observation with several hundred people to find headaches as well as gastric disturbances entirely relieved by proper refraction or wearing appropriate glasses. I may go still further and speak of the vast number

> of nervous patients in whom the neurotic symptoms have entirely disappeared by relief of eyestrain or ocular treatment.

Dr. Howard F. Hansell, Philadelphia, writes:

> I believe that sick headache is one of the symptoms of eyestrain, and I have known patients that were cured by ocular treatment.

Drs. Stockton, Starr, F. Park Lewis, Pohlman, Phillips, Hubbell of Buffalo, Jackson of Denver, Ellis of Los Angeles, Roberts of Pasadena, Westcott of Chicago, Willetts of Pittsburg, Lovett of Langhorne, Pa., Ball, Sherman of Cleveland, M. N. Bemus of Jamestown, N. Y., Spalding of Portland, Maine, Alleman of Brooklyn, N. Y., Pyle and Thorington of Philadelphia assent to the following: "I believe that sick headache often depends on eyestrain, and have known cases that were cured by ocular treatment."

Subnormal accommodation, I suspect, is far more common than is supposed, and I have suggested that it largely accounts for our failures, as oculists, to cure migraine. I have reported a number of cases in which correction of this weakness, besides the distance glasses, as bifocals, alone enabled me to cure in many most distressing cases of sick headache. One was that of a boy of 12, with most alarming and continuous vomiting. Despite my best distance-correction, the pernicious vomiting came on daily when he began to study. By adding 1.50 D. to his distance glasses as a (premature) presbyopic or bifocal segment, there was instant and permanent relief. I have prescribed bifocals in a healthy child of 9 years of age, in which the premature presbyopia was from 1.50 to 2.00.

I could give the details of perhaps a thousand cases of "migraine" or sick headache cured by glasses. I should say that 90 per cent. of cases are immediately curable, and a large proportion of the rest curable in time, and so soon as the secondary systemic functional effects have been overcome. A few cases are incurable, because these secondary effects have become organic or too chronic to allow any cure. There are also rare cases in which mental reaction has become impossible.

Of the skeptics, cynics, ultraconservatives, who smile derisively at all this, I wish simply to ask by what right, ophthalmic, neurologic, humane or human, by what logical or scientific right, they dispute the testimony of Piorry, William Thomson, R. Brudwell Carter, Savage, Lauder Brunton, Hewetson, Ranney, Stevens, G. Martin, Gould, de Schweinitz, Toms, Callan, Stephenson, George H. Thomas, Farman, Zimmerman, Libby, Derdiger, Claiborne, Snell, Myles Standish, Allen Greenwood, Edwin E. Jack, E. P. Morrow, Cheney, Burnside Foster, S. D. Risley, Carmalt, Bennett, Southard, John Green, Carhart, Weeks, Baker, Brav, Pronger, Gallant, Jarrett, Hansell, Stockton, Starr, Lewis, Pohlman, Phillips, Hubbell, Jackson, Ellis, Roberts, Westcott, Willetts, Lovett, Ball, Bemus, Spalding, Alleman, Pyle, Thorington and others? These men report many hundreds, doubtless could report thousands of cures of severe or "typical" migraine "by means of the relief of eyestrain." Are these men unworthy of belief? Are they not as honest and as scientific, as good physicians as the deniers? The conclusion must be that if the deniers have not seen such results they have not done the kind of work which produces the results. Negative testimony is in such cases utterly valueless as against the positive testimony of those who have seen the results. Conform to the rules of science, play the game fair, and the exhibits will prove the thesis. If it is said, "True, but exaggerated," then is the admission more condemning than the pooh-pooh or the denial. "How true?" we then ask them. Demonstrate the limit; verify the little admitted! Show the exaggerators up as pseudoscientists, and even as liars. Convince the poor, tormented millions you can't cure, that the hope held out to them is a delusion. How they will thank you! And remember that if you err too much or too little, by so much as a grain in getting your exact pound of flesh, woe to you! There is this hour more personal wretchedness and torment caused by "migraine" than by all the combined diseases of the world. It not seldom causes death, indirectly, secondarily, but still absolutely. If you fail to save one life that might be saved, what is it but murder? But prolonged suffering for a lifetime, and of the most atrocious kind which migraine produces, is worse than death. If relying on you, if by neglect, if by a glib and spurious science, one sufferer fails to find a possible cure, yours the infamy! God may not exist, and professional ethics may prove a delusion, but justice will look out for the man who takes the health and happiness of his brother in his hands and wrecks them with the sneer of callous ignorance!

RESPIRATORY MOVEMENTS OF THE BRONCHIAL TUBES.*

E. FLETCHER INGALS, M.D.
CHICAGO.

Last summer while doing bronchoscopy on a child about 2 years of age for the removal of a foreign body from one of the branches of a main bronchus, my attention was arrested by the rhythmical dilatation and contraction of the main bronchi and their branches during inspiration and expiration. This movement was so great that in inspiration the diameter of the tube was sometimes more than twice as great as in expiration. Similar movements were shortly afterward observed in the trachea, also in another young child, although I had not observed these movements in three adults on whom I had done the operation. From this fact I surmised that the movements were not present in the larger bronchi of adults for the reason that they were prevented by the greater rigidity of the cartilages, but it seemed probable that they extended throughout the smaller bronchi at all ages. A more recent operation on a boy of 13 showed that the respiratory movements, even of the main bronchi, were very well marked at that age. I did not notice such movements in a girl of 17, but in that case I unfortunately did not observe whether or not they were present in the first divisions of the bronchus. Last August, aided by a student of medicine, Mr. W. W. Hamburger, I made some experiments on a dog in the physiologic laboratory of the University of Chicago to acquire further light on this subject. The animal was of medium size, weighing 6.5 kilos, and was about 10 months old. It was thoroughly anesthetized by morphin and chloretone. The anesthetic was administered by a stomach tube, and consisted of chloretone gram 1.3 and morphin gram, 0.3 dissolved in 50 c.c. of a 50 per cent. alcoholic solution.

Mr. Hamburger did tracheotomy. On inserting the bronchoscope we found that the main bronchi and all of their visible branches expanded and contracted regularly with inspiration and expiration, the diameter of the tube in contraction during expiration being only from two-fifths to one-half of that at the end of inspiration. We placed two ligatures on the right vagus and cut between them. We then found that the movements of the bronchi still continued, though apparently within a narrower range; but on stimulating the distal end of the divided nerve with a weak electric current, the contractions were more pronounced, and they continued for several seconds until the stimulation was discontinued.

---

* Read before the American Climatological Association, Detroit, June 28-29, 1905.

In this experiment, by stimulating the vagus nerve, the caliber of the bronchus was reduced from one-fourth to one-third of its diameter during inspiration. These observations indicate that while the movements were in part passive—that is, the result of the bellows movement of the chest wall, which, as Professor Stewart states, is well understood—they were also in part dependent on muscular contractions resulting from the action of the vagus nerve. A more recent experiment of my own on a smaller dog, apparently 2 or 3 years old, showed that the movements of the main bronchi continued at that age and that the contraction of the muscles in the first branches were in some instances so great as to cause complete collapse of the tube.

I was unable to find references to this action of the bronchi in any of my own medical works, but Prof. George N. Stewart of the University of Chicago and Prof. Jacques Loeb of the University of California kindly gave me several references to the mostly brief paragraphs or sentences referring to this subject in physiologic writings. Professor Stewart, in a personal letter, says:

> Longet[1] showed that the vagus contains motor fibers for the bronchial muscles as early as 1842. Donders[2] stated that in deep respiration the bronchi became wider and shorter in inspiration and narrower and longer in expiration. Einthoven[3] and Beer[4] have investigated carefully the innervation of the bronchial muscles. More recently, Dixon and Brodie[5] have shown that the vagus contains both constrictors and dilators[6] for the bronchial muscles, which can be excited directly and reflexly. Whether this mechanism is in action in normal respiration is not discussed, to my knowledge, by any of these recent authors, and the whole question . . . has been rather neglected by systematic writers. Such direct observations as you have made have not found their way into the physiologic literature, if any are recorded, and yet they have a distinct interest for physiologists. In the paper just cited, Chauveau[7] is quoted as stating that "in the horse the bronchioles show some tonus which disappears on section of the vagus, for he found that if the vagus be cut on one side, the vesicular murmur on that side disappears, and it is weakened on the opposite side."

Dr. J. Gordon Wilson of the Hull Laboratory (Department of Anatomy), University of Chicago, has taken up the investigaton of this subject with me, and has kindly furnished me an extended abstract of Einthoven's article.[8] This article extends through eighty pages and appears to cover everything that is known on this subject. Dr. Wilson writes:

> The movements of the bronchi have been investigated repeatedly, but the results are conflicting. The results of Einthoven, as well as those of Dixon and Brodie, were obtained by artificial respiration. Their experiments were directed to measuring the air-volume of the lungs during the phases of respiration under specified conditions; thus Dixon and Brodie enclosed a lobe of the lung in a metal oncometer and so measured alterations in volume during respiration. The bronchoscope offers another point of attack. It affords an opportunity of directly observing the movements of the bronchi under what must be regarded as more normal conditions. It may be regarded as satisfactorily shown that constrictor fibers for the bronchial muscles run in the vagus nerve. But so many anomalous conditions have been observed after stimulation of the peripheral end of a divided vagus nerve that many have concluded that not only constrictor fibers for the bronchial muscles are present, but that broncho-dilator fibers must also lie in this nerve. Einthoven denied the presence of such dilator fibers, but the recent work of Dixon and Brodie seems to show that such fibers must be present to explain the results obtained. Whether or not this explanation is entirely satisfactory still remains to be seen.

Einthoven especially has pointed out the important part these muscles may play in disease, especially in asthma. But he concludes that "the significance of the bronchial muscles in normal respiration is small; and what use the bronchial muscles have, what causes their presence and development, we venture no conjecture."

Dr. Wilson suggests that "although the bronchoscope has its limitations, since the finer bronchi are beyond our view, yet there are other points which it may enable us to investigate. Among others it should be possible to observe whether tonus exists in the bronchial muscles, disappearing on section of the vagus, as is claimed by Chauveau and denied by Einthoven and by Dixon and Brodie. It should be possible to observe the effects of peripheral stimulation on the bronchi and the immediate action of the most active drugs."

I can hardly approach this subject except from a clinical standpoint, but Dr. Wilson has taken up the investigation with me, and I hope that we may accomplish something. In the meantime, I hope that research workers will also take up this work by which some valuable facts should be discovered.

The first question suggested to my mind is, what influence has this action of the bronchial tubes in the production of the physical signs heard over the lungs? The statement of Chauveau just cited offers a possible explanation, entirely different from that generally accepted, for the production of the vesicular murmur.

I have seen several cases, most of them in the last stage of diphtheria, where, although the respiratory movements seemed normal and the bronchioles and air cells appeared to be free, the vesicular murmur was absent and the signs impressed me as due to paralysis of the lung itself. Although I could not understand such a condition, I have cautiously suggested it to two or three medical friends, but without obtaining any information.

I have recently examined a patient who has been subject to asthma all her life, who said that she had had one, two or three attacks every day or night for years. In this case, in an interval between paroxysms, the vesicular murmur was not more than from one-sixth to one-fourth as loud as normal in either lung, although there were no râles and no signs of vesicular emphysema or other disease of the lungs. The question arose in my mind whether the feebleness of the vesicular murmur was not due to deficient innervation of the bronchial muscles, and whether the attacks of asthma might not be due to irritability resulting in excessive paroxysmal action of the contractile muscles analogous to the action of the myocardium in palpitation; and somewhat analogous to the excessive contraction of the abductor muscles of the vocal cords that close the glottis, which seem to retain their function longer than do the muscles of abduction, in some cases of paresis of the recurrent laryngeal nerve.

This action of the bronchial muscles probably has much to do with the production of râles in bronchitis. We are familiar with the contractions occurring in inflamed muscular fiber, and this may explain more sat-

isfactorily than has been done heretofore the multitudinous more or less persistent râles heard in acute bronchitis, whether these râles be dry or moist.

I have often asked myself how air can be drawn into bronchial tubes filled with mucus, but I thought I could understand how it could be forced out if it once got in; however, by the same reasoning I was unable to satisfy myself why all of the smaller bronchi and the air cells did not on the advent of inflammation of the bronchial tubes become speedily filled with secretion or else collapsed. The theory that the ciliary motion on the surface of the mucous membrane toward the larger tubes carried the secretions upward and outward never appeared to me satisfactory; but if my hypothesis is correct, it explains how the pumping action of these tubes, in connection with the movement of the air, can readily accomplish this result. If experiments should ultimately show us that this contraction of the bronchi in expiration begins at the periphery and works toward the larger tubes, as from analogy we may readily believe, we will then know how the secretions are evacuated from the air cells and the smaller bronchi. The same line of thought brings us to a new viewpoint in studying the sudden development and subsidence of râles in asthma. The respiratory movements of the bronchi and their dependence on muscular activity explain the sudden accession of attacks of asthma resulting from irritation of the pneumogastric nerve, and also show us why inhibition of this action quickly relieves the distressing dyspnea.

We are taught that the bronchial breathing heard in pneumonia is the normal sound of the tubes better transmitted to the surface in consequence of the solid medium. This has never been to me a satisfactory explanation, but I can now understand how the consolidated lung by preventing the bronchi from contracting will yield the characteristic tubular sounds that we find in pneumonia like those produced in a metallic or other rigid tube.

Paresis of these muscles may account for some of the phenomena of pulmonary edema. Impairment of this function may also account for the curious cases that we sometimes meet of functional dyspnea, while lungs, heart and kidneys yield no evidences of disease. The severe attacks of dyspnea in renal disease also may possibly be in part dependent on interference with the respiratory movements of the bronchi.

Dr. Norman Bridge informs me that from personal experience and from the testimony of intelligent patients he several years ago became convinced that the bronchi were relatively collapsed in expiration, and that as a result, the phlegm could be raised at the end of expiration by a gentle explosion of cough and with not more than a quarter of the usual blast of air of a coughing effort. This indicates the importance of this function in relieving the distress of some persons afflicted with pulmonary tuberculosis, especially when from weakness they have difficulty in expelling the sputum.

The difficulties experienced in discovering small objects in the bronchi through the bronchoscope, even under bright illumination, are doubtless largely due to the action of the bronchial constrictor muscles, which may possibly completely close the tube in which the foreign body is ensconced. A recent experiment on a dog appeared to demonstrate the correctness of this hypothesis. In that case, after demonstrating the bronchi and their movements to a class of students, I dropped a pin, head downward, through the bronchoscope into the lung. Although it was very easy to see a pin that had been dropped into the hollow of my hand tightly closed about the end of the bronchoscope, I had very great difficulty in finding the pin at all in this experiment; indeed, I searched for it with the greatest care for fifteen or twenty minutes, but was unable to see it . Finally, I passed down beyond the bronchoscope an instrument termed a pin finder, which I had devised for the special purpose of bringing a pin or other small object into the center of the lumen of the bronchus. Turning this gently about a few times, I thought that I felt the pin; then, crowding the bronchoscope down a little farther so as to encompass the upper portion of the pin finder used in the search, I withdrew the instrument, and inserted a small electric lamp, which enabled me to see about one-fourth of an inch of the pointed end of the pin projecting into the lower end of the bronchoscope, while the remainder of the pin was completely hidden apparently by complete collapse of the bronchus.

The experiments made by Dr. Wilson and myself have been done on dogs, anesthetized with either morphia or chloroform, or both. The experiments are only in their initial stage, and not yet sufficiently numerous to enable us to arrive at definite conclusions. They bear out my observations, however, about the rhythmical dilatation and contraction of the bronchi during respiration. In quiet inspiration the smaller tubes can be seen to dilate to twice the diameter they have during the respiratory pause; during the expiration following they almost close.

Stimulation of the peripheral end of the sectioned vagus nerve produces constriction; at times the immediate result appears to be a dilatation—a result which Dixon and Brodie obtained also. Similar results have also been observed after stimulation of the mucous membrane of the nose. We hope to continue these investigations and, later, to be able to report the result more fully.

We believe that the action of remedies may be profitably studied through the bronchoscope in the living animal, and that as a result of such study we shall doubtless obtain much more intelligent and effective therapeusis in some affections of the heart and lungs.

Important observations on the effect of drugs on the bronchial muscles have been made among others by Einthoven, and by Dixon and Brodie. The latter investigators classify certain drugs as broncho-constrictors, others as broncho-dilators.

As a result of their investigations, Dixon and Brodie have arrived at the following conclusions, among others:

1. The inhalation of ether or chloroform for anesthetic purposes abolishes the effect of the vagus on the bronchioles. This is due to the paralysis of the nerve-endings by direct absorption through the mucous membrane.

2. Reflex bronchiolar constriction is best obtained by exciting the nasal mucous membrane. Little or no result has been obtained by stimulating the sciatic, central end of the vagus, superior laryngeal or cornea.

3. Gradual constriction of bronchioles followed by dilatation is usually seen postmortem.

4. Muscarin, pilocarpin and physostigmin excite the vagal endings and induce typical bronchiolar constriction, the effect of which is abolished by atropin.

5. Barium, veratrin, bromin and the salts of many of the heavy metals (e. g., gold) produce constriction, which is not influenced by atropin.

These facts are suggestive in the therapeusis of many cases in which expectoration is difficult.

6. Inhalation of CO_2 leads to constriction of the bronchioles, which is not altogether central in origin.

7. Chloroform, ether, urethrane, lobelia and atropin induce dilatation of the bronchioles when constriction is present. The dilatation produced by lobelia is very transient, while that by atropin is permanent.

These facts should aid us materially in relieving spasmodic asthma.

A CASE OF IMPERFORATE RECTUM WITH ABSENCE OF THE ANUS.

EDWARD H. SMALL, A.M., M.D.
PITTSBURG, PA.

Oct. 25, 1903, R. K., male, was born under my care. His mother had already given birth to four other children, all perfectly formed. He was born at full term, head presentation, R. O. A. No anus at all was to be seen. The raphe ran from the base of the scrotum to the tip of the coccyx. There was phimosis and the second and third toes of both feet were webbed. There was a slight dimple in the medium line of the back over the center of the sacrum. The base of the penis was drawn toward the scrotum, making it much longer anteriorly than posteriorly. The mother is disposed to attribute these malformations to a rather severe felon she had seven months before the child's birth.

When the boy was 30 hours old he was held in the exaggerated lithotomy position, and, without the use of anesthesia, a trocar, one-fifth inch in diameter and two and one-half inches long, was thrust by Dr. J. A. Hawkins into the perineum where the arms should have been and in the direction in which the rectum should have been, into the hollow of the sacrum. When the trocar was about all introduced, lack of resistance was noticed, the stylet was withdrawn and meconium came out through the canula. As soon as the meconium ceased to flow, the canula was withdrawn, the bowel was washed out with an enema containing olive oil and the opening was enlarged with a knife sufficiently to allow the introduction of the little finger. The rectum could easily be felt at the bottom of the wound. The bowel seemed to be firmly attached to the surrounding tissues, so that it was not thought best to attempt to pull it down and attach it to the external wound. The bowel was situated about two inches from the perineum. A soft rubber catheter, 20 French, was inserted through the wound into the rectum and left there, secured with a safety pin. Absorbent cotton was placed over the perineum, held in place by a diaper. The rectum was so firmly attached to the surrounding parts that it was not at all displaced by these manipulations.

In five hours the baby was resting quietly. The next morning the catheter was withdrawn and some meconium was discharged. The bowel was washed out and the little finger was inserted into the rectum, causing some bleeding. The rectum at this time seemed to have descended a little toward the perineum. The catheter was reinserted and left in. On the evening of this day the baby refused to nurse, his temperature was 102 and he was in a state of collapse. The next morning he was better and tried to nurse. The catheter was withdrawn, the bowel was washed out and the wound was dilated with the little finger, causing some bleeding. Same procedure in the evening.

On the following day the mother's milk supply failed and the baby was put on modified milk.

At the end of the fourth day no bleeding was caused by the dilatation with the finger. On the fifth day the baby passed feces for the first time. The wound was thus dilated with the finger night and morning for eleven days. At each insertion of the finger the rectum seemed to have descended nearer and nearer to the perineum. The catheter was kept in the wound for only five days. On the eleventh day the use of the finger as a dilator was stopped, meatus sounds, 30, 35 and 40 French, being used instead.

The baby did not do very well on the modified milk, and for several weeks we despaired of raising him. At the end of a month the sounds were used but once a day, then every other day, then once a week, and finally but once a month. At the end of two months the rectum had descended almost to the perineum.

Now that the boy is over 20 months old, the mother says that the movements from his bowels are the same as those of her other children when at his age. As a rule, he lets her know when his bowels are to be moved.

On examination the anus is somewhat funnel-shaped. The sphincter is in good working order; in fact, practically perfect, but is about one-half inch higher up than normal. A person examining him now, not knowing what the condition at birth had been, would find his anus about the same as that of any other child. The dilators are used now once a month, but they cause no pain. It is probable that their use might safely be discontinued.

This case belongs to the third species of Bodenhammer's[1] classification of the congenital malformations of the rectum and anus. In all the cases of which I have read I can find no one treated exactly as was this one. We were very fortunate in the outcome, and probably would not be so successful again. Bodenhammer advises against the use of the trocar in these cases, but recommends dissection with the knife until the rectum is found and then its pulling down and attachment to the external wound in the perineum.

Jacobi gives a case in which he put in a trocar and meconium oozed from the wound. He then put in a dilator and dilated the wound, but in two days death resulted from peritonitis. A postmortem showed that the trocar had passed into the bowel, but also into the peritoneal cavity, into which the meconium had escaped, giving rise to peritonitis.

He also says that there are several ways in which this malformation may occur. The anal orifice in the fetus is formed by an invagination of the outer surface, the tube thus formed meeting and uniting with the rectum. The septum between the two tubes becomes absorbed and the lumen of the tube is complete. Now, sometimes the septum does not become absorbed. It may exist at the anal orifice itself, obstructing the bowel at its very entrance; or, again, the anus itself may be normal, yet this septum may exist unabsorbed some distance up the bowel, an inch or an inch and one-half. Here the ends of the tubes have met and united, but the septum has not been absorbed.

Again, the two tubes may not meet at all, but may be separated altogether by areolar tissue (as in my case); or, again, instead of meeting end to end, they may meet sidewise and so touch only at one point, as in the case given above, in which the trocar entered both the bowel and the peritoneal cavity.[2]

The great objection to the method of simple puncture and incision in complete obstruction is that it exposes the tissues, especially the peritoneum, to septic infection. In my case antisepsis was as carefully carried out as possible. The fact that the gut was so firmly attached to the surrounding tissues greatly aided the good result. Here some of the fibers of the sphincter and levator must have been present and some of the areolar tissue between the bowel and perineum must have become absorbed, allowing them to come together.

My case well supports Bodenhammer's dictum, that in the newborn time and long experience have taught us that nature is more capable of greater adaptation than in adults, and that in the young child the original defects of development are subsequently compensated, if art will only give a helping hand in accomplishing her purpose. The surgical treatment of these malformations has been most exhaustively treated by Rudolph Matas.[3]

THE PSYCHOSES OF HEART DISEASE.*

WILLIAM HOUSE, M.D.
Resident Physician Mt. Tabor Nervous Sanitarium.
PORTLAND, ORE.

The task of classifying the psychoses caused or aggravated by disease of the heart is not easy. Eliminating organic disease of the brain, it is probable that disease of the heart is responsible for more cases of psychic disturbance than is disease of any other organ. It is notable that but brief attention is accorded to this etiologic phase of insanity and allied psychoses by text-book authors, probably for the reason that heart disease is in most instances regarded as a result or simple complication and not as a cause. A further explanation of the possible oversight rightly to place heart diseases in the etiology of mental disturbances is that, primarily, the psychic phenomena of the milder forms of heart trouble, such as palpitation, are usually insufficient to constitute insanity and are looked on as unimportant. Secondly, the severe forms of heart disease producing active mental disturbance, incapacitate the victim for undue violence, weaken his power of decided physical activity, and constitute an excellent reason for his treatment in the wards of a general hospital where his mental infirmities are regarded as subordinate to his physical ones, with the result that, while the latter are carefully considered, the former are usually regarded as of small consequence. I do not at all take issue with this method of caring for such cases, believing that it affords opportunities for treatment that are as good as, or better than the public asylum, in which the organic phenomena are not unlikely to be subordinated to the purely psychic, with the result that the latter, or symptom, is treated, while the former, or cause, is apt to receive scant attention; and in the forms of psychosis due to severe heart disease, it appears that treatment directed at the physical infirmity is after all the essential thing, so that such cases are valuable more for comparative and etiologic purposes than for therapeutic reasons. But in the milder forms such reasoning is distinctly bad, for the mental disturbance must not only be carefully analyzed, but treated coincidently with the cardiac disease, whether that be organic or functional. And it is important to trace the relationship between the two, as to which is cause and which effect; for it is certain that if cardiac disease can cause mental disturbance, no less can mental disease cause cardiac disturbance, as witness the irregularities and palpitations easily produced in neurasthenics by suggestion.

It is possible to divide the psychic disturbances of heart disease according to their etiology into those due to:

1. Local sensations usually not painful, whereby the patient becomes aware of some cardiac abnormality, as in palpitation, irregularity, tachycardia, bradycardia or excessive loudness.
2. Local pain, as in angina pectoris, endocarditis, pericarditis, or compression from pericardial effusion.
3. Disturbances in circulation.
    a. Vasomotor constrictions.
    b. Feebleness of heart's action with cyanosis.
4. Secondary lesions in the brain.
    a. Embolism from valve lesions.
    b. Edemas and effusions from incompetency.

From the standpoint of symptoms the psychic phenomena of heart disease may be divided into:

1. States of fear or apprehension, usually accompanied by more or less panic, and alternating with some depression and irritability, without being accompanied by active delusions or hallucinations.
2. Delusions founded on misinterpretations of local cardiac phenomena, such as pain.
3. Active hallucinations and delusions from circulatory disturbances involving sensory organs.
4. Dementias from secondary lesions in the brain.

In such classifications as the above it must be remembered that one division may shade into another imperceptibly. Any of the symptoms of the second classification may occur with any of the causes of the first, and, indeed, the symptoms of any of the various subdivisions may be associated with one another with kaleidescopic possibilities. And yet it may be said that as a result of Class 1 of the first classification the symptoms of Class 1 of the second are the symptoms most likely to be encountered. In like manner the second class of each classification will most frequently be found related, and the third and fourth classes likewise, but to a less extent. It will be found, however, that the symptom of fear is commonly found in all the subdivisions and classes.

To Division 1 of the first classification belong all those cases of cardiac palpitation and irregularity witnessed in neurasthenics. In these cases the heart usually presents no evidences of abnormality when the patient is at ease, except that it is somewhat hypertrophied and rapid. Attacks of palpitation come on without warning or apparent cause. At other times disturbances of rhythm result from excitement, emotion, or gastric disturbances. Often at night the patient awakens with a violent start, finds his heart beating like a trip hammer, rises to a sitting posture, grasping his chest, and becomes apprehensive, irritable, excited, incoherent and irrational. Following such an attack he develops what might be called cardiophobia, living in constant fear of a recurrence, and not infrequently working himself into a state of excitement resulting in severe tachycardia or palpitation, with an intensification of the fears and doubts of preceding seizures. He demands close attention, sympathy and repeated assurances of safety, and is afraid to be left alone. After an attack the patient is sleepless, morbidly depressed, emotional and irritable.

Case 1.—J. M., aged 26, born in U. S., farmer, entered sanitarium in June, 1904. A typical neurasthenic. Physical appearance rugged. No evidences of organic abnormality except increase in rapidity and loudness of heart sounds. While on half-rest treatment, was awakened one morning from nap by violent palpitation, accompanied by great terror and anxiety. I saw him within ten minutes and found his pulse 140, heart slightly irregular, no murmurs. Face was pale, terror stricken and wet with perspiration of fear. He insisted he was going to die and demanded attendance and encouragement for one-half hour, when his heart having ceased to beat so violently, he became calm. He had numerous similar attacks during his stay with us.

Case 2.—C. L., aged 38, born in U. S., politician and postmaster. Physical appearance remarkably healthy. Heart sounds accented and frequency from 92 to 100, ordinarily. Saw preceding case in attack described, and within twelve hours experienced seizure bearing striking similarity. The attack was repeated about every third night, usually around 2 a. m., and patient refused to go to sleep without first being visited, when assurances that he was all right and free from danger calmed him. The next day he was always more restless and emotional than before the attacks, and for months lived in terror of them. He has since recovered sufficiently to perform his official duties.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-sixth Annual Session,

In the first of these cases the cardiac disturbances acted as a stimulus to the excitable nervous system and bore the very distinct relation of a cause for the intensified psychic phenomena. In the second case apparently suggestion produced palpitation and thus the heart trouble might reasonably be regarded, at least in part, as due to the psychic disturbance.

Not only may these disturbances of rhythm with abnormal mental phenomena be witnessed in ordinary neurasthenics, but also in pronounced degree do they occur in the cases of so-called Pennsylvania heart of Stockton. These cases are seen in their most classic aspects in lumbering regions, where men subject themselves to great strain for long periods, achieve cardiac hypertrophy, and follow it with complete cessation from hard work. As a result the heart becomes irritable and subject to attacks of palpitation and rapidity. The seizures in many instances are accompanied by minor disturbances of mind as witnessed in the following case:

Case 3.—L. L., lumberman, aged 44, born in U. S., admitted to county hospital in 1895. Physical appearance robust. All organs normal except heart, which was hypertrophied and rapid, about 120 per minute. On exertion he developed palpitation and became excited and apprehensive. Following attacks he was irritable and quarreled with nurses and attendants, patients and physicians. Was unruly and refused to obey orders. Finally dismissed for insubordination. Was at all times fully aware of his physical infirmity and its dangers, and when free from attacks, tractable and obliging, but declared that he could not control actions described with seizures.

In another subclass of cases there is more pronounced cardiac disturbance and likewise more marked mental phenomena. A typical example of such was Case 4.

Case 4.—C. J., aged 28, born in Germany, cook. Admitted to County Hospital, Feb. 13, 1896. Present illness began five days ago with vertigo, pain in chest over heart, and dyspnea. The slightest exertion causes patient to become so weak and tired that he is obliged to go to bed. He states that effort is followed by coughing spells, which last until he has had a rest of several hours. Examination: Heart is enlarged, 92 per minute. While undergoing examination heart suddenly became exceedingly rapid and irregular, first sound being bell-like in tone. There is no murmur. Patient grasps chest, breathes hard, face expresses intense fear, actions emotional, articulation indistinct and sentences incoherent. Following this, he was seized with convulsions, from which he could be aroused by sharp orders and threats. The seizure thus presented many of the classic phenomena of hysteria, with decided departure from customary hysterical or normal mental actions. While under care, these attacks were repeated a number of times and it was noticeable that the cardiac disturbances preceded the mental in every instance. The administration of nitroglycerin was uniformly followed by prompt improvement in pulse and mental symptoms. There was at no time pain in the region of the heart. With rest and nitrites the patient's condition was such that he was able to resume work in a month. The visiting physician, a well-known consultant in New York state, diagnosed this case as "nervous heart" and later "neurosis of the cardiac ganglia," a striking commentary on the possibilities of nomenclature to conceal ignorance of exact conditions.

Passing on, one comes by natural processes to false and true angina pectoris and in these cases witnesses some of the most interesting but distressing phenomena of mind associated with heart disease. The following case is unique in my experience:

Case 5.—Male, aged 37, single, admitted to Manhattan State Hospital May 15, 1897. Born in Ireland. Foreman of excavating gang. Temperate. Family history good. Repeated attacks of articular rheumatism. On admission, was excited and hysterical. Burst into tears when being questioned and said: "I am worrying for the sins I have committed. Adultery and other sins, sir." Appearance depressed and melancholy. Body somewhat emaciated. Pulse weak and running 160 to 180 per minute. Apex beat diffuse and two inches to left of nipple in greatest intensity. Relative cardiac dullness much increased. At apex, sounds were loud and bell-like. There were no murmurs, but sounds were transmitted to axilla, and all over chest were heard with metallic intensity. When patient moved the heart became irregular and more rapid, and this was always accompanied by mental excitement. While under care, patient experienced a number of attacks of mild cardiac pain with what he called "rheumatism" of his left shoulder, and at such times always became emotional, hysteric, incoherent, irrational and finally maniacal, but amenable to some degree of control. An ice bag to the chest, rest in bed and the use of heart tonics and vaso-dilators invariably produced quiet.

Eliminating those cases of true angina pectoris in which during the attack there is fear of death—which is well founded and therefore not properly to be regarded as abnormal—there are yet some cases of angina pectoris in which the repeated attacks have produced psychic disturbances such as are illustrated by the following:

Case 6.—P. C., aged 32, admitted to County Hospital March 28, 1896. Alcoholic and heavy smoker. Had grip and pericarditis two years ago. Entered for treatment of acute bronchitis. While convalescent, developed attacks of angina pectoris with terrific pain. He was often able to inhale as much as 1 dram of nitrite of amyl without relief, which finally came only with chloroform anesthesia. Attacks were accompanied by terror, excitement and incoherence of speech, and following these he became offensive and obscene in language, threatening and unreasonable until sleep came on, from which he awakened quiet, tractable and with but partial remembrance of the events of the seizure.

Misinterpretation of local cardiac sensations and delusions built thereon was well witnessed in two cases in which the pathologic conditions were similar. The mental phenomena were fairly typical of two somewhat opposite phases of insanity, yet bore in each case striking relationship to the degree of acuity and character of the general symptoms.

Case 7.—J. K., aged 62, laborer, admitted to County Hospital February, 1896. Examination showed consolidation of posterior portion of base of left lung, which was diagnosed as bronchopneumonia. Heart 84 to 92. Temperature 101 to 102. Mental disturbance pronounced, but differed from ordinary febrile delirium to such an extent that he was looked on by the visiting physician as an insane case in which the lung trouble was simply an accident. He was confused and incoherent in speech, muttered constantly, was sleepless and declined food. He refused to lie down, declaring that a huge vise was clamping his heart and that he must sit up to watch it. Also that electric currents were coming up through his bed magnetizing the vise. His facies was typical of a low form of acute mania, and his general conduct corresponded. He died at the end of a week, and necropsy disclosed an unexpected purulent pericarditis, with about four ounces of pus. There were numerous adhesions binding the apex of the heart to the pericardium in front. The fluid, although small in quantity, really distended the sac, and it was easy to understand the production of symptoms, resulting almost logically, one might say, in his delusions.

Case 8.—W. L. L., aged 62, German, admitted to County Hospital May 15, 1905. There were the characteristic physical signs of bronchopneumonia of left base. Within a week he became depressed and melancholic and suffered from insomnia. Talked to himself and ate but little. After two weeks was able to be up about ward and appeared to be influenced by hallucinations of sight and hearing. His heart was about 116 to 120, and during the night he frequently complained that weights were put on his chest whenever he lay down to sleep. The mental state was one which I have since frequently observed and considered as mild simple melancholia. He died suddenly forty-four days after first visit. Necropsy showed purulent pericarditis with 16 ounces of pus and enormous distension of pericardium. The lung was not involved except by compression.

In Cases 7 and 8 sepsis unquestionably influenced the mental state, yet clearly the cardiac lesions were responsible for the character of the resulting delusions.

The preceding cases illustrate throughout phases of mental disturbance dependent on abnormal sensations in the region of the heart, and except in the last two cases, recognized by the patients as due to disturbance of that organ. But there is a distinct class of cases in which, though the heart is diseased, the patient is unaware of it, and yet has pronounced mental symptoms directly traceable to the organic heart trouble and in no sense due to the secondary organic consequences thereof. Of such are the following:

Case 9.—W. M., aged 19, male, well educated. Mental trouble, judging from history, dated back one month, when he left home for a neighboring state to seek work. He was there arrested, charged with insanity and brought to our sanitarium in November, 1904. On admission, he was depressed, melancholy, delusional, and suffered from auditory hallucinations. There was a faint murmur over the aortic area, probably due to slight stenosis, but not at that time regarded as of importance in relation to the mental phenomena. With rest, patient became cheerful and improved. After a few days he complained of cold and numbness in extremities and hands and feet were found blue and cold to touch. The heart murmur was louder than at first, the melancholic depression greatly aggravated and accompanied by suicidal tendencies. Regarding the cyanosis as due to vasomotor disorder, belladonna was administered. There was prompt disappearance of the peripheral cyanosis, an improved pulse and a return to a more nearly normal mental condition. Withdrawal of belladonna was followed after a few days by return of the cyanosis, this time with a feeling that the hands were dead, and accompanied by aggravation of mental symptoms with hysterical outbursts. Belladonna again relieved the cyanosis, and its disappearance was followed by decided mental improvement. After four months patient showed evidence of beginning dementia with continual auditory hallucinations.

This case I regard as one of dementia præcox, having an hereditary basis, with the cardiac disease as the distinct exciting cause of onset.

During the time Case 9 was under care we had another patient with a double mitral murmur, whose mental phenomena were typical of acute mania.

Case 10.—Mrs. H., aged 56, married, no hereditary influence. Recently removed from the East to Oregon. Had lost her home in fire previously, had brooded much over this misfortune and weight was considerably reduced. One week before admission to the sanitarium, she became suspicious, quarrelsome, and finally, while laboring under a delusion, assaulted her husband. On admission she was maniacal, incoherent and sleepless. Was anemic and had temperature of 101. The heart was exceedingly irregular with double mitral murmurs and typical gallop rhythm. There was no edema and no evidence of focal cerebral involvement, such as might have been due to embolism. Patient was put in resting sheet and fed through nasal tube. No improvement for several days. Digitalin was then administered by hypodermic, and as the heart's action gradually became steady, the mind improved coincidently. She had several relapses with excitement, increase of delusions, vivid hallucinations of sight and hearing, and the performance of irrational acts. In each instance these attacks were preceded or accompanied by recurrence of the cardiac irregularity; in several instances the attacks were directly traceable to undue physical activity. With tonic treatment, in addition to the digitalis, cardiac compensation was restored, and in six weeks the patient was taken home by her friends, quiet, tractable and orderly.

The relation of the heart and mental diseases was here unmistakable. The shock of loss of home followed by transplantation can scarce bear the relation of more than predisposing elements. Loss of appetite followed, then dilatation of a weak and diseased heart. Insomnia and the mental phenomena were the logical outcome. There was striking contrast in the symptoms of these two latter cases, in that the outbursts of excitement in the vigorous and independent old woman were substituted for the hysterical, helpless attacks of the constitutionally weak natured boy. In his case also there was an astonishing relation between the asthenic cardiac disease, the feeble circulation, and the slow, depressed, and confused mentality. While in her case there was exhibited a violent, restless, active and racy mind which but kept pace with the irregular riotous circulation, and galloping, tempestuous heart.

Coming to the last class are first, those cases of embolism in which valvular vegetations are the cause of organic brain lesions. Such cases are too frequent and well recognized to need comment and it is safe to pass to the remaining group, in which the secondary results of heart disease, the arterial dilatations and tortuosities, edemas and toxemias, result in mental disturbances which, were they not associated with unmistakable heart disease, would be classed as true insanities.

The variations in these cases are numerous, but in the main certain more or less distinctive symptoms are recognizable. The first of these are ocular and auditory hallucinations. The former are doubtless due to tortuous retinal arteries, often albuminuric, and are of a vividness comparable only to the hallucinations of sight in acute alcoholism, in which the immediate cause, i. e., arterial dilatations in the retina, appears to be identical. Occasionally the auditory hallucinations occur independently, but for the most part they are founded on the ocular misconceptions and interpretations, and on both a series of delusions is based. The remaining cases illustrate this well.

Case 11.—C. N., aged 37, German, was brought to County Hospital Jan. 21, 1896, because his family found it impossible to keep him longer at home owing to outbursts of excitement and violence. On admission, he was suffering from endocarditis with insufficiency, and had dropsical limbs. Mental phenomena were insomnia or restless sleep, from which he was disturbed by haunting dreams. He insisted that he had just seen his wife enter dormitory and heard her speak to the nurses and other patients. Declared that she refused to speak to him, but waved her hand derisively, and on this basis built up an elaborate system of delusions of her infidelity and persecutory attitude toward himself. This statement, with slight variations, was repeated daily until death occurred two months after admission. Contradiction invariably resulted in violent excitement, accompanied by incoherent, abusive and blasphemous language, followed by great exhaustion.

Case 12.—M. G., aged 46, German, admitted to County Hospital July 22, 1895. Had double aortic murmur and mitral insufficiency. With the gradual development of dilatation and edema, patient became restless and irritable. He complained of strange visitations, claiming that he saw people in the ward who went out through the windows, hooting and shouting at him. On this he constructed a series of delusions of persecution involving other patients, nurses and physician. He lived nine and one-half months after admission, alternating but little from a steady and gradual progession of heart symptoms, with as regular an accompaniment of the mental phenomena, until about one month before death, when he became partially demented.

The gross postmortem findings in the two immediately preceding cases were edema of the limbs, abdomen, and brain. The heart conditions substantiated the findings of the physical examinations.

Case 13.—W. B., aged 44, German, formerly a hard drinker, was brought to sanitarium because his family was unable to keep him at home, as he was noisy, excited and delusional. Had well-recognized heart disease. On examination he was found to be suffering from general edema. Heart dilated with loud mitral insufficiency murmur. He slept badly, groaning and muttering. Usually awakened with a start and an appearance of fright. Spoke of seeing people in the room and heard them talking about him, but, as a rule, indistinctly and not unpleasantly. Unwilling to take medicine for fear of poison. Very irritable, cross at times, confused. Was under care seven weeks, and died two days after an embolism of the left middle cerebral artery, this being confirmed by autopsy.

Throughout the histories, in the interests of brevity, all extraneous matter has been omitted. In some of the cases cited there were possible hereditary and other etiologic elements. It is not my intention to regard such details slightingly and in every instance the aim has been to describe both heart and mental symptoms in a manner to best show their relationship to each other. It is not contended that the heart disease in every case was the sole cause, but rather that it was the exciting cause, except wherein the cardiac troubles were rather the effect, and to this attention has been called. Especial insistence is placed on the relationship of mental improvement to therapy directed against the heart trouble. In selecting the histories, only cases under personal observation were used, and no reference has been made to the cases of heart disease occurring in the chronic insane, for there is no reason why insanity should protect against such accidental complications. Also less than one-half the actual histories preserved with a view to presenting a paper on this subject have been used, for the reason that in many cases the relationship between the heart and mental disease was obscured by some other trouble, as in one case of alienation due apparently to aortic aneurism and endocarditis, in which there was a history of syphilis. In the absence of positive knowledge to the contrary, it was assumed that there may have been a syphilitic cerebral lesion. An extremely interesting case under care as this paper is being completed has also been omitted. In this case the patient came under care with highly acute maniacal symptoms. His heart was examined, as well as his active movements would permit, and no murmurs discovered. When, after a week, the excitement somewhat subsided, it was noticed that his respirations were rapid and his lips cyanosed. Examination revealed a loud mitral insufficiency murmur and great dilatation. From his wife a history of articular rheumatism was obtained, together with the statement that he had been rejected for life insurance three times because of heart disease and accepted on different occasions by three other companies. Under the circumstances it seems probable the murmur depended in part on dilatation under the strain of the maniacal excitement and thus was a pure and simple complication. It is noteworthy that even here, as soon as the lesion was discovered and digitalis used, the cyanosis disappeared, the murmur softened, and the improvement in the expansive and confused mentality was markedly accelerated.

All the cases cited, with one exception, were observed in a general hospital or private sanitarium. During a residence of nearly two years in one of the largest of our state hospitals, over one-half of the time on the receiving service, I observed but few of these cardio-mental cases. The obvious deduction is that such cases, as suggested in the beginning of this paper, are usually treated by the internist and not by the alienist, and I am sure that, as a result, the psychic side has been minimized. I do not regard any of these cases as unusual, rather believing them typical examples of comparatively common disease forms, and I desire only to recall your attention to them as being almost as much within the province of the psychiatrist as the internist, and to commend them for closer observation than the literature indicates they have received.

DEFECTS OF WILL FROM A MEDICAL STANDPOINT.*

HOWELL T. PERSHING, M.D.
DENVER.

At first my subject may seem too intangible to be of importance in practical medicine; but one has only to think of his cases of alcoholism to realize that complete recovery or absolute ruin may be determined by the operation of the patient's will. Analogous cases in which a morbid appetite needs control at once suggest themselves, and when we further recall the many disturbances of voluntary action from which hysteric and neurasthenic patients may suffer the great importance of the subject is manifest. But, granting the desirability of remedying defects of will, some may ask whether we have any definite knowledge of the nature of volition and of its defects, such as a physician can utilize in the actual treatment of patients. I am convinced that there is a great and growing fund of such knowledge which, if carefully considered by any physician, will help him to be a better therapeutist.

The will, of course, is not to be regarded as a mysterious metaphysical entity, or even as a faculty, but as a cerebral process, accompanied, it is true, by consciousness, but nevertheless a nervous mechanism whose operation is modified by various conditions in health and often very seriously deranged by disease. Recent knowledge of the localization of motor, sensory and psychic functions in the cortex makes it possible to form a fairly definite and highly probable hypothesis as to what the mechanism of volition is and to deduce from it important clinical precepts.

The essential effect of willing is to cause motion, and when we inspect our own minds we find that a voluntary motion is always preceded by the idea of the motion. Now, ideas have definite locations in the sensory centers of the cortex, each according to its kind, ideas of form and color in the visual centers, of sound in the auditory centers, and so on, and each idea is the memory of a sensation. The ideas of motion are located in the kinesthetic centers in the posterior part of the Rolandic region and are memories of the sensations caused by motion. The memory or idea of any particular motion is the cause of that motion being repeated.

Suppose, for example, that one sees an orange on the table and picks it up. Something like the following must occur in the brain: Nerve currents, starting from the eyes, reach the visual center (V, Fig. 1), and these arouse sensations of form and color, which, in association with certain ideas of distance, solidity, weight, etc., constitute the visual perception of the orange. Association impulses then pass from the visual center to the kinesthetic center for the right hand (K), arousing in it the memory of past sensations caused by the motion of grasping a similar object. If the idea of this motion is strong and vivid, that center (K) is correspondingly excited and sends association currents forward to the motor centers (M), and these centers, becoming active, send currents down through the pyramidal fibers which cause the muscles to contract. I say something like this must happen, for the sketch, of course, is far simpler than the reality, and the processes of association, which I have represented as direct, are probably roundabout by way of the higher centers of Hughlings Jackson or the association centers of Flechsig. Flechsig thinks that the prefrontal and parts of the parietal and temporal regions of the cortex are central stations which connect the motor and sensory centers somewhat as a telephone central connects the scattered subscribers; hence, he has called them association centers.

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Jackson's earlier theory of a higher representation of motions and sensations and Flechsig's seem to me to be in essential harmony with each other and with the facts indicating that the prefrontal lobes are essential to the higher mental operations. They are also in harmony with the theory of a concept center in the temporal lobe, as held by Dr. Mills. Nevertheless, for the sake of clearness, we may provisionally represent association impulses as passing directly from one center to another.

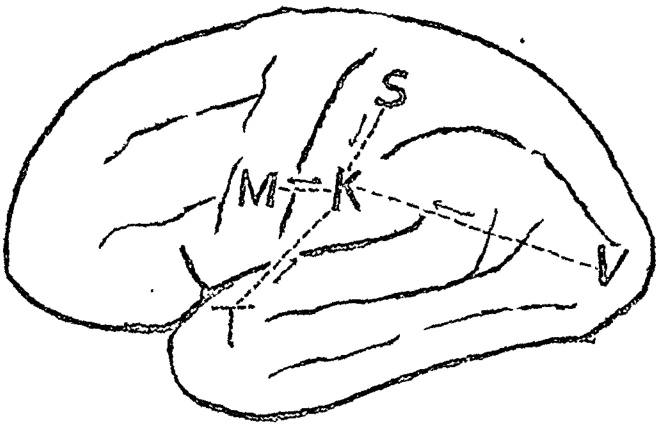

Figure 1.

We see, then, that voluntary motion is ideomotor action and is brought about by a chain of cortical reflexes; that activity of the kinesthetic center is essential and results, on the side of consciousness, in the idea of the motion to be performed, and, on the physical side, in the excitation of the appropriate motor centers.

Other reflexes are subject to both acceleration and restraint, and so it is with volition. Suppose that perception of the orange revives in the center (which we will call T) the memory of its aspect, agreeable to taste. Then the idea of grasping it is strengthened by accelerating impulses passing from T to the kinesthetic center (K) and the motion is made more prompt and certain. Suppose, on the other hand, that the sight of the fruit revives the memory of colic. The center for abdominal pain (which we may represent as S) then sends inhibiting impulses to K, which weaken the idea of grasping, and perhaps S may also excite in the adjacent center K′ the idea of withdrawing the hand, so that two opposing motions are begun in the muscles. When both accelerating and inhibiting impulses thus act on the kinesthetic center at the same time or in rapid alteration, their joint result is arrested action of indecision until one or the other finally predominates.

The action of this volitional reflex and the effect of its accelerating and restraining impulses is subject to many modifications, depending principally on habit, instinct, emotional state and stage of mental development.

Habitual acts are more readily caused by the exciting idea than others and are harder to restrain, because the nervous paths have been facilitated. Instinctive acts occur even more readily, because they have been habitual in the race and the brain paths are especially prepared for them at birth.

Certain emotions, such as joy and anger, set the ideomotor regions of the cortex in a quiver of excitement and favor immediate action in response to ideas, with no time for restraining impulses to interfere. We see extreme illustrations of this state in certain stages of intoxication by alcohol or ether and in an attack of acute mania. Grief and despondency, on the other hand, weaken the ideomotor regions and favor all restraining impulses, so their tendency is to indecision or absolute inaction. The extreme illustration of this state is found in melancholia, more particularly in melancholia attonita. The effect of fear varies: ordinary ideomotor action is depressed by it so that we can say one is paralyzed by fear, but the instinctive motions of defense or escape may be enormously accelerated by it, as may well be seen in melancholia agitata and the active phase of alcoholic insanity.

In immature minds the ideas necessary to the execution of complex and difficult actions and those necessary for the restraint of simple and instinctive actions are weak or absent.

From this statement of fact and theory a rule may be deduced which has a great many practical applications. The idea of an action tends at once to cause it; think strongly of a certain word and you will find your tongue stirring to utter it, of a blow and you will find your fist clenching. If the action is desirable, first make the idea of it as definite and vigorous as possible and then favor its effect on the motor centers by accelerating ideas and by raising the emotional tone. If the action is undesirable try to prevent the idea of it from occurring at all, and only as a second choice rely on restraining ideas or depressing emotions.

All prohibitions of specific acts have the disadvantage that they must first awaken the idea of the act and so tend to cause it. Restraining impulses may come into play, but the mechanism is started and they may be too feeble or too late to arrest it. Better incite to doing what will exclude the wrong. The reformed alcoholic or drug habitué or young man trying to avoid sexual errors should not keep repeating vows or assurances that he will not offend again. A wise physician will often make light of his patient's past sins in order that forgetting them he may "press forward toward the mark of his high calling." Rewards are far more efficient than punishments; they fix attention on what is desirable and at the same time raise the emotional tone. They have an especially important place in the treatment of nervous children. Give a child a reward for speaking correctly, for sleeping soundly, for having a nice, dry bed, for easy and graceful motions, and it will succeed vastly better than punishment for failures.

The treatment of hysterical paralysis is a most interesting application of the general rule we have deduced.

We remember the admirable epigram: "She says, 'I can not;' it looks like, 'I will not;' but it is 'I can not will.'" Now, if we inquire in what respect the will is defective we come on the great fact that the paralyzed limb is always more or less anesthetic to touch, pain and temperature, and more particularly to kinesthetic impressions. There is convincing proof that this loss of sensibility is cortical; the sensory center K, while not organically damaged, has been so depressed that it is no longer sufficiently excited by the sensory currents coming up from the affected muscles and joints. Still less is it excited by association currents from other cortical centers; the patient can not revive the idea of the motion; an essential part of the process of volition is absent. It is inexcusably coarse work simply to tell such a patient that the paralysis is hysterical and that she could move the limb properly if she only wanted to. She feels that this is not true, and it really is not.

After such a thorough examination as will in itself inspire confidence we should proceed, according to a definite plan, first to raise the emotional tone by a highly favorable prognosis; then to excite the depressed sensory centers by electrical stimulation and passive motion of the affected limb; then to further awaken the lost idea of motion by encouraging the patient to aid rhythmical passive motions by voluntary effort. Often there are inhibiting ideas of pain or danger that will arrest the desired motion, as we will know by seeing the opposing muscles contract; these ideas may be dispelled by repeated assurances and other appropriate methods. The one fundamental thing is to reawaken the lost sensations and ideas in the kinesthetic center.

Of the opposite hysterical phenomenon, spasm, I shall not speak further than to say that the general spasms and some of the localized ones are not voluntary motions, but instinctive reactions constituting part of an emotional process. They may, however, be counteracted by strictly voluntary motions which tend to exclude them, as well as by rational attempts to improve the emotional state. Some of the localized spasms are voluntary, although not desired by the patient, inasmuch as they depend on a fixed idea of the abnormal posture and are to be corrected by dispelling the idea.[1]

In strictly neurasthenic states, although we never see such paralyses or spasms as are common in hysteria, the disagreeable sensations and the limitation of spontaneous mental action, due to exhaustion, lead to several distinct forms of deranged volition.

(1) Ordinary duties become excessively difficult, because the normal pleasurable sensations attending mental work have been banished by fatigue and in their place unpleasant feelings have become associated and exert an inhibiting effect. Williams James gives a vivid account of how a college professor will pass the forenoon doing a multitude of trivial things, "anything rather than do the one thing he ought to do, prepare for a lecture on formal logic, which he hates." The remedy for this state is rest, especially from the distasteful work, together with measures to invigorate the nervous system generally.

(2) Actions of various kinds become associated, perhaps accidentally, with a definite, although utterly irrational feeling of fear, which inhibits the action. Thus a tired neurasthenic will often walk a long distance, seeing himself passed by car after car, each of which he thinks of boarding, but does not do so on account of fear. One of my patients, secretary of an insurance company, is often unable to sign policies in the presence of the clerk who is waiting for them. He has a feeling like that of stage fright, his hand trembles and he makes a specious excuse. Alone he does much better, but is still troubled. Similar cases could be multiplied indefinitely. The treatment of such a condition, in addition to those measures favoring rest and recuperation which are generally required in neurasthenia, should include special means of securing emotional tranquillity and repeated encouragement to attempt graduated exercises in doing those things that have become associated with morbid fear.

I have already considered this at some length in a paper read at the New Orleans session.[2]

(3) In some cases the weakening of spontaneous cortical activity and the tendency toward unpleasant feelings and ideas cause the accelerating and inhibiting impulses of an every-day action to be so evenly balanced that indecision is indefinitely prolonged. Thus a neurasthenic will start out to get his breakfast which he very much needs, but can not choose the restaurant, some trivial objection to each, in turn, being sufficient inhibition, although the idea of getting breakfast can not be dismissed.

(4) The weakening of spontaneous mental activity explains another form of defect in which the patient feels an impulse to do unimportant and useless things, such as counting, touching posts or other objects, jostling a stranger in the street, etc. In a healthy brain such ideas, no doubt, occur from time to time, but are immediately crowded out by other interests. In the neurasthenic the idea of the action has the center of the field of consciousness, and no other has sufficient vigor to crowd it out. As long as it remains without the motion being performed there is a feeling of unrest and distress; once the action is performed there is relief, and the brain is free to act in some other way. The familiar case of Dr. Samuel Johnson going back to touch the post he had passed is an illustration. The remedy for such defects of will is not to tell the patient, what he already knows, that the impulse is irrational, but to cure the neurasthenia and especially to restore the normal spontaneity and tone of feeling. As to the impulses themselves, they are generally to be resisted by an attempt to become interested in other things, but the patient must not be too strenuous in his resistance; excessive struggles not only lead to exhaustion, but fix the intruding idea more immovably than ever in the exhausted cortex. Where no grave question of conduct is involved, it may be better to yield and forget. Oscar Wilde's scandalous saying that the only thing to do with a temptation is to yield to it at once and so deprive it of its power of torment was, no doubt, suggested by the distress attending this form of arrested volition. One of my patients, a very intelligent lady, once had an impulse to stop and count all the objects in a jeweler's window, but was determined not to be so foolish and walked on. The window was in her mind all day, and late in the evening, restless and unhappy, she concluded that there could be no peace of mind for her until she went back to the window and counted, which she did, at great inconvenience to herself and her husband.

(5) The last form of disturbance of will in neurasthenia is typified in such a case as this: A father sees his child and a carving knife at the same time, and the

---

[2] Pershing: The Treatment of Emotional Disturbances. Journal A. M. A., Jan. 30, 1904.

thought comes, "What if I should cut my child's throat?" No doubt, equally perverse thoughts come to healthy persons, but they are not taken seriously and are quickly displaced by the flood of normal mental activities and so forgotten. But in the irritably weak brain there is an excessive emotional reaction; the patient feels his heart bound and then stop, he trembles and is bathed in sweat. He has the sensations of fear and, as he interprets it, he is afraid that he may murder his child. The intensity of his horror fixes the incident in his memory; the same idea is recalled again and again until everything seems to be associated with it. The patient feels that the idea of the action tends to cause it and has no confidence in the restraining influences. Such cases are extremely difficult to treat successfully and will generally tax all the resources of the most skillful neurologist. The important elements of treatment, in my opinion, are (a) the thorough mental and physical examination that will prevent the physician from mistaking melancholia or any other disease for neurasthenia and at the same time make the patient feel that his case is understood; (b) positive assurance that the dreaded act can not be committed; (c) general measures toward the cure of neurasthenia, especially rest, food, tonics. cultivation of normal interests, perhaps change of scene; (d) the skillful use of opium in order to secure emotional rest, with all possible precautions in view of the danger of a habit.

It is evident that what has been outlined in this article might be greatly amplified and also that much not touched on might have been included, but I think enough has been said to show that the modern psychophysiologic theory of volition has important applications in practical medicine.

DISCUSSION.

Dr. D. R. Brower, Chicago, said that the relation of the will in these mental cases has always been a matter of very great consideration to him. He thinks that the great majority of mental cases begin in will disturbances, and that the failure to recognize this beginning is one reason for the want of success in the treatment. After the case has progressed for a time the will defects are overwhelmed by the emotional defects. He agreed with Dr. Pershing as to the correction, so far as practicable, of these defects. Dr. Brower's experience, like Dr. Pershing's, has been that opium given so that the patients do not know they are taking it is one of the best agents in giving tone to this apparent defect, provided the opium is properly guarded by other agents to prevent interference with the important function of elimination. Dr. Brower is quite sure that in the past he has overlooked the beginning of many cases, because he has failed thoroughly and carefully to consider the importance of this matter.

Dr. H. A. Tomlinson, St. Peter, Minn., said that probably inadvertently Dr. Pershing failed to refer to that portion of the cerebral cortex that is anterior to the precentral fissure, the center for general inhibition. It is both interesting and instructive in studying the comparative physiology of the nervous system, and especially the evolution of its functions, to note that the primary function of the nervous system is motor; that is, the generation of motor impulses in response to the afferent stimuli resulting from the irritability of the dermal layer of cells. Also that these impulses have for their object the approximation of the animal to food substances, or the avoidance of obvious sources of danger. As the number of animals in a given area becomes greater, the sources of danger more numerous and less easily avoided, and the competition more keen, the necessity for an inhibitory or dirigent apparatus arises; which is identical with what we call the volitional function in the higher animals. Passing from this primitive association of functions, and ignoring the primary function of reproduction, to the complex functional arrangement and association in the human nervous system, there is evident an enormous elaboration of these simple processes, with their correlations in the different cortical areas in the central portion of the cortex, which Dr. Pershing calls the kinesthetic centers, into which stimuli are received, and from which motor impulses are transmitted, and which the environment of the human being has made necessary. The great complexity of the environment, however, makes necessary another functional area, which has to do with the relation of impressions from without; the inhibition and direction of the resulting afferent impulses. This is the process of volition, and, so far as we know, this function resides in the cortex of the frontal lobes, anterior to the precentral fissure. The association and continuity of the cortex of the second and third frontal convolutions with the ascending frontal; and the association of these convolutions with the operculum, inferior parietal lobule, and the anterior portions of the first and second temporal convolutions, shows how the function of inhibition is intimately connected with the higher activities, and dominates those impulses that control the relations of the individual with his environment. There is negative proof of this relation in the progress of the processes of cortical degeneration, which begins first in the frontal lobes, then the areas referred to above, and next the paracentral lobule and the angular gyrus. In cases of defective development, too, it is in the area of the prefrontal lobes that the deficiency is most marked, and the reversion in type most conspicuous. Just in proportion as these parts of the brain cortex are lacking in development, or are degenerated, will the changes described by Dr. Pershing be apparent. Now in order to get a definite idea of the pathology of these conditions, where no gross lesion exists, we must study the circulation in the cortex, especially the lymph and venous circulations, and their influence in the production of autointoxication. It is an interesting hypothesis that circulatory disturbances following autointoxication result in the breaking up of the normal relation of impressions, and that the consequent futile activity of the kinesthetic centers brings about extreme fatigue of the cortical cell, therefore imperfect reconstitution, and the subsequent neurasthenia that shows itself in volitional aberration.

Dr. G. R. Clark, Dearborn, Mont., called attention to the fact that in the insanity of adolescence many of the patients exhibit peculiarities, for example, an impulse to touch certain things, or to go upstairs backward. This only occurs at times, but it is one of the characteristic signs of the disease. Such a patient may be sufficiently cured to pass out into the world again, but during the course of the disease his mind has acquired a sort of mental habit for the reproduction of that particular mannerism. The clearing up of the symptoms is remarkable, but after a few months or years of the old associations and the old manner of thinking the mannerisms will return. Dementia præcox may be secondary to certain vasomotor conditions; the nervous system may have lost its power of stability. When these patients are 50 years old or more they are likely to acquire new mannerisms, and anything which tends to destroy the physical health to a certain extent brings back this old tissue instability. Dr. Clark referred to a certain form of dementia præcox seen in school children in which the child is supposed to be only dull and stupid, he is punished for a condition for which he is not responsible.

Dr. J. Allen Gilbert, Portland, expressed his disappointment that Dr. Pershing did not take up the subject of the will more as the will. It is a psychologic subject through and through, and the more Dr. Gilbert studies the more he is convinced that any arbitrary division or classification of psychic functions will lead us into trouble. Neurologists forget at times, he said, that there is no emotion without will and no will without intellect, and no intelligence without emotion and *vice versa*. In other words, psychic activity, as such, is unitary. The more he studies physiologic psychology the more he is convinced that it is utterly impossible to use any classification which bases physiologic psychology strictly and solely on a material basis. He referred to Ziehen's "Physiological Psychology" as a work most heavily laden with inconsistencies and contradictions. Haeckel's "Riddle of the Universe," by which so many physicians swear, he considered likewise overburdened with self-contradictions. Professor James, who might be considered the father of the theory of emotions based on material processes, has retracted his own theory as erroneous and untrue to the facts. Dr. Gilbert is as yet unwilling to admit that psychology has no place other than as a corollary to physics.

Dr. H. T. **Pershing** said that of course he realized that in bringing up such a subject he was opening up an enormous field where one might easily go astray. He was forced by time limitations to give only the barest details of the subject and there were many things which he had to omit entirely. Many of those perversions of the will are the reversions to the primitive type of the child; thus Dr. Johnson touched his post as he went along, just as the boy at certain intervals kicks at everything he passes. In reply to another criticism Dr. Pershing said that the nature of consciousness is a subject on which he is always willing to talk, but it is a subject that can hardly be included in a discussion on medicine. Consciousness does exist and it is interfered with in disease of the brain; and the effect of disease on the consciousness varies according to the location of the lesion in the brain. Therefore, whatever the metaphysical implications one can not fail to see the practical relations of these facts. He said that the assumption that the mind is a unity seems to him false; the mind is as complex as the brain, and very far from being a unity. Dr. Pershing would deny the assertion that there can be no operation of the will without operation of the intellect. He was surprised to hear that Professor James has gone back on his theory of the emotions, but even if he has, Dr. Pershing will believe that the theory is well sustained. It does not depend on James alone, but on Lange and other psychologists as well. James, however, gave it a particularly happy expression in his text-books on psychology.

Dr. J. H. **McBride**, Pasadena, Cal., declared the mentality of the patient and the physical environment are vital matters. Medical men have not given this subject the attention it deserves. In all forms of nervous diseases, the mental influences that are brought to bear on the patient are important, or may be important elements in the treatment. So far as the will is concerned, he is inclined to shy at it. The discussion of it furnishes a certain amount of mental gymnastic, but he is not certain that we are further benefited. Huxley, who was fond of psychologic subjects, said that when, in his discussions, he got to the will, he always quit.

A STUDY OF PERFORATION IN TYPHOID FEVER.*

RICHARD H. HARTE, M.D.

PHILADELPHIA.

This subject is of interest to every physician and surgeon on account of the great prevalence of typhoid fever as a disease and the apparent unavoidable frequency with which this extremely fatal complication of intestinal perforation occurs.

It has been estimated by Briggs that more than 16,000 perforations of the intestines due to typhoid fever occur annually in the United States alone. I am inclined to think this statement rather too high, however. From some carefully prepared statistics made by my colleague, Dr. J. Alison Scott, in reference to the frequency of this disease in the United States during the year 1900, based on the United States Census Report, he found that 35,379 persons succumbed to the disease. From the analysis of autopsies of 10 large hospitals it would appear that one death in every four was due to intestinal perforation. Assuming, therefore, that one death out of every four is due to perforation, 8,844 perforative cases occurred throughout the entire country in the year 1900. Assuming that the mortality of all the operative cases is 75 per cent., timely operation in these 8,844 cases might have yielded 2,211 recoveries. These are important figures and mean the loss or saving of many lives.

CAUSES.

The causes of perforation are numerous. Among them may be mentioned race, sex, age, season, geographical location, stage of the disease, severity of the attack, intestinal parasites, etc.

Race.—It would appear that the white race is more disposed to perforation than the negro race, but this is a questionable statement as a larger percentage of cases occur among the white race, and consequently more perforations are found in them.

Sex.—The male sex is more liable to suffer perforation than is the female, the ratio being about 4 to 1. Fitz collected 100 cases of perforation in which 71 of the patients were males.

Age.—Typhoid fever is as a rule a disease of youth or early adult life and therefore the largest percentage of perforations will naturally be found at what is considered an early age. In 279 cases where the age was known over 12 per cent. occurred in patients under 15 years of age; 54 per cent. occurred between 15 and 30 years of age, and 33 per cent. occurred in patients over 30 years of age. Two of my own cases operated on were children under 12 years of age.

Season and Geographical Location.—These are not important factors. In the summer season more perforations occur simply because typhoid fever is apt to be more prevalent at that time of year. The majority of my own cases, however, occurred between the months of February and June.

Stages of Disease.—It would appear from a careful analysis of a large number of cases that the third week in the disease is the most usual time for perforation. It may occur, however, at any time during the height of the disease, as pointed out by Dr. Osler; it may have occurred before the patient feels at all sick, as has been noticed in a number of ambulatory cases operated on; it may occur during convalescence, when every danger of the disease is supposed to have passed.

Severity of the Attack.—There is no doubt that certain epidemics of typhoid fever are more virulent in character than others; the invasion of the Peyer's patches in such cases seems to be much deeper and more extensive, and perforation is much more likely to occur than in the cases of milder type.

Intestinal Parasites and Exciting Causes.—Intestinal parasites may be a predisposing cause and even rarely an exciting cause to perforation. Many of the earlier reported cases of perforation in the stomach were due to intestinal worms, and it seems possible that these parasites may be an exciting cause to typhoid perforation. Virulent cocci or bacilli may produce a secondary infection, resulting in inflammation and necrosis. A severe inflammatory process of an ulcer thus infected may lead to perforation. The exciting causes of typhoid perforation are, however, generally mechanical. Anything which sets up an unusual peristaltic action is likely to cause solution of the continuity of the already diseased intestines; undue or involuntary contraction of the abdominal muscles, straining at stools or urination, sudden spasm, cough, the struggle or spasm incident to a cold bath, should all be mentioned in this connection. There is no doubt that irritating particles of food, for instance, apples and other articles brought to the patients by their friends, should be classed as exciting causes. When, however, perforation occurs while the patient is sleeping, and without exciting cause, it is generally supposed to be due to excessive necrosis.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

PATHOLOGY.

The pathologic lesions in typhoid fever are especially prominent in the last three feet of the ileum, although extensive lesions may also be found through the colon even down to the sigmoid, as was noticed in a case operated on at the Pennsylvania Hospital. In the beginning there is a congested condition of the mucosa and follicles of the lower ileum. The accumulation of cells in the lymph tissue may be so extensive that the adjacent mucosa becomes infiltrated, and the blood vessels becoming more or less compressed cause the follicles to assume a white or anemic appearance. There may be an appreciable round-celled infiltration. If the so-called medullary infiltration does not result, coagulation necrosis becomes discharged in the bowel. The process is aided by the direct action of typhoid toxins and also by the ischemia produced by the choking of the vascular channels and partly by the direct action of the typhoid toxins. Recently these toxins have been regarded as agents producing the agglutination or thrombosis of the erythrocytes in typhoid. The thrombosis predisposes to sloughing. When the medullary infiltration involves the entire thickness of the bowel it is evident that a perforation will occur when the necrotic area is separated. The sloughing may involve only the mucosa, or, as is more common, the tissues down to the muscularis. The slough is cast off about the end of the second or beginning of the third week of the disease. Separation begins at the end of the necrosed area, but it is rare to find an entire Peyer's patch that is completely sloughed away, or to find a perfectly ovoid ulcer directly opposite the mesenteric attachment. When the ulcer fails to heal and gradually deepens as it approaches the peritoneal coat, it may induce more or less plastic peritonitis which, when found on the surface of the bowel, is always suspicious of an incipient perforation. After its removal a small opening into the bowel can be detected, varying in size from the point of a pin to the size of a lima bean. Nature not infrequently attempts to close these openings by the wall of the bowel agglutinating itself to another portion of the bowel or by a tag of omentum which has become adherent around the opening. A specimen in the Pennsylvania Hospital Museum shows perfectly where a typhoid perforation was closed by this means, the patient dying of a subsequent illness.

If the process be not arrested at this point, an abscess will form; and cases have been reported in which an abscess was not opened for two or three months subsequently, the patients ultimately recovering. If, however, no adhesions form, then perforation into the free peritoneal cavity takes place, and general peritonitis results. Even in cases of perforation arising after this manner, the size of the bowel opening may be great, or several small perforations may form in the floor of the same ulcer. At times it almost seems as if the stage of medullary infiltration persisted throughout the disease, since in cases of perforation from ulceration the surrounding parts of the perforated Peyer's patch sometimes are so thickened and friable that it becomes impossible to make sutures hold; whereas, at other times the bowel has become so thinned by extensive ulcers that it appears like paper. At times, too, it is impossible to tell whether the perforation has arisen from sloughing or from progressive ulceration.

As to the form of the perforation, the larger circular lesions are, as has been stated above, generally due to sloughing; the smaller, or cribriform, to ulceration; and the oblong, slit-like perforations have been thought to be due to traumatism.

The perforation is usually situated on the part of the bowel diametrically opposite to the mesenteric attachment, where the lymph glands of the intestine are found and where the blood supply is poorest. Occasionally, however, an ulcer will perforate between the layers of the mesentery and a retroperitoneal abscess will be formed. Such a lesion may be mistaken for a suppurating mesenteric gland.

In 190 cases in which the site of perforation is mentioned, it was found within 12 inches of the cecum in 140, or 73 per cent.; and in only 4 cases, or 2.1 per cent. was it more than three feet distant from the ileocecal valve. In seven cases only was the colon perforated, five times the ascending colon, once each the transverse colon and the sigmoid flexure. Meckel's diverticulum was perforated three times, and the appendix eight times.

BACTERIOLOGY.

With regard to the bacteriology, it has been found that in cases where the typhoid bacillus alone is the infecting cause, the usual lesions are a low-grade peritonitis, frequently lemon-colored exudation, few adhesions, and not much lymph. Where the streptococci or the staphylococci abound the lymph is more abundant, and adhesions are the rule if the peritonitis has lasted more than a few hours. The prognosis is much more grave in the streptococcic infection than in the typhoid.

SYMPTOMS AND DIAGNOSIS.

In what may be called a typical case, the symptoms are well marked and easily distinguished, but unfortunately such a case is the exception. It is well known, however, that not infrequently a case may present all the clinical evidences of perforation, submit to operation and no intraperitoneal irritation whatever be found. On the other hand, patients may die without any abdominal symptoms of importance, and at autopsy a perforation may be found. Nevertheless, there are certain classical symptoms which must be carefully borne in mind and which must be thoroughly analyzed in every case of suspected perforation, for without doing this errors will be made in the diagnosis.

Pain.—Pain is a very frequent and common symptom of perforation in typhoid fever. It is usually of a stabbing character, situated most frequently in the lower right quadrant of the abdomen, but is also sometimes felt in the epigastrium and umbilical region, not unusually in the bladder, and, in the male, at the end of the penis. These facts should not be overlooked in patients who are apathetic or who are so far advanced in the typhoid disease that they feel no pain. Thus, it often happens that the first evidence of perforation is a distended abdomen with movable dullness in the flanks. The pain of perforation is usually severe and sometimes will last for a while and then disappear without any apparent reason, but as a rule it is a constant symptom throughout the onset of the perforation. I recall a case where the first sign of perforation was a violent attack of pain, causing the patient to scream out and draw his legs up in bed. This lasted for but a short time and then entirely disappeared, so that this symptom was entirely absent later on, leaving only a muscular rigidity on which to base the diagnosis. On the other hand, it must be borne in mind that pain is such a constant and varying thing during a typhoidal attack, due to ingestion of imperfectly digested food, flatulence, or to a dozen and one causes of irritation within the lumen of the gut, that this symptom must always be carefully guarded.

The greatest care must be exercised in patients who are suffering from pleural irritation. A short time ago I saw a case where violent pain and muscular rigidity were dependent upon a diaphragmatic pleurisy. It was with some difficulty that this condition was isolated, but when treated by straps all pain and symptoms subsided in a short time. The muscular rigidity incident to the pain was very marked and deceiving. I recall two other cases, one in which there was violent pain, collapse, sweating, and all the symptoms of a perforation, caused by the sudden passage of a renal calculus. In the other the patient was a negro suffering from an acute pleural pneumonia. He had all the symptoms of perforation, but it was thought that these were caused by the pleural condition. Later, however, operation was decided on and revealed a perforation in the intestine, which had been the original cause of the symptoms, not the pleural condition as was supposed. This mistake resulted in a great loss of time, which, of course, materially influenced the prognosis. Therefore, I emphasize the fact that the greatest care must be exercised in regard to this very important symptom of pain.

Sweating.—Either alone or accompanied by the pain of perforation, and followed by a fall in temperature, sweating is in itself always a significant fact. The sweating may be profuse, involving the whole body, but is more often confined to the head and neck. The fall in temperature is a question over which much discussion has arisen. In my experience I regard it as a most valuable sign, and where it has not been recognized, I believe it is simply due to lack of careful observation on the part of the nurse or attendants. Therefore, all cases of temperature should be carefully recorded from time to time, and any variation, especially a fall, should be a source of warning and the medical attendant should at once be notified. A fall in temperature is, of course, a very frequent accompaniment of intestinal hemorrhage during typhoid fever, but the hemorrhage as a rule is painless and is usually evident in the stools in the course of an hour or so.

Vomiting.—This so frequently occurs in severe cases of typhoid fever without any exciting or apparent cause, that it can not alone be considered indicative of perforation, but where it occurs for the first time and especially where it either precedes or follows pain, it should not be lightly passed by. If at all violent in itself it may cause a perforation, and in many instances follows it.

Rigidity.—Rigidity of the abdominal muscles is the most valuable of all signs in the diagnosis of intestinal perforation. This is a rigidity which is reflex, and hence involuntary, and depends for its production on the overflow of stimulus received from the lumbar cord from the inflamed peritoneum and is usually observed in the right rectus and oblique muscles of the abdomen, although it may extend over the entire abdominal surface. Voluntary rigidity of the abdominal muscles is often present in typhoid fever, due to the endeavor of the patient to protect the sore and swollen intestines from pressure and unnecessary manipulation on the part of the attending physician or surgeon. I would say here that the sense of rigidity, which is conveyed to the hand of the examiner, is of varying quality, depending on the examiner's delicate sense of touch, and what may be regarded by one as distinct rigidity may be regarded by another as unappreciable. I do not think that all physicians realize what is meant by a surgeon as abdominal rigidity. Some will press the fingers deep into the patient's abdomen, as though they were attempting to palpate the lumbar spine, and then declare they can not detect any rigidity, whereas the skillful examiner, who is endowed with this valuable gift, *tactus eruditis,* will detect—seemingly by a mere touch of the finger tips—the slightest rigidity which may be present, and which may have escaped the grosser sense of touch of the less skillful examiner.

Tenderness.—Tenderness is by no means so valuable a sign as rigidity, for not only may tenderness exist where no perforation is present, a fact which every physician of experience well knows, but it may also be absent when perforation does exist, as was exemplified in the last case on which I operated. The explanation of this may be found in the apathetic state of the patient, the typhoid toxins having entirely benumbed his sensibilities.

Pulse Rate.—Along with the cardinal symptoms which have just been mentioned, namely, pain, rigidity and tenderness, there is, in the vast majority of cases, an increase in the pulse rate. The usual pulse rate in typhoid fever ranges from 80 to 100 beats per minute, but after perforation this pulse rate usually rises rapidly from 120 to 140 in a surprisingly short space of time, often within 10 or 15 minutes after the onset of the pain.

Countenance.—The change in the facial expression, which follows intestinal perforation, is most important. Almost at the very moment of perforation there is a distinct change of expression difficult to describe, but yet easily recognized when once seen. It is not the peritonitic facies which closely approaches the Hippocratic in type, but is distinctly characteristic of the shock of perforation. It is what the French call an "abatement" of the countenance, consisting in a general weakening of the expression.

Dullness on Percussion.—This is a very uncertain sign, and palpation of the liver dullness on which so much reliance was placed in former years is even more elusive. Mere intestinal distension frequently produces palpation of the hepatic dullness, and even when air is free within the peritoneal cavity the liver dullness may persist. Dullness in the flanks can not be considered as pathognomonic of fecal extravasation, since when the colon is freely movable liquid feces within it may give rise to a similar condition.

Examination of the Blood.—This procedure, which has been so frequently discussed, is very deceiving. In the last two cases operated on at the Pennsylvania Hospital the leucocyte count was only 5,000, and it would, therefore, seem in these cases as though the patient's exhausted condition prevented a leucocytosis. During typhoid fever the number of leucocytes is physiologically diminished, and although an extremely high leucocytosis may render positive the diagnosis of perforation, a low count should under no circumstances be interpreted as showing that no perforation exists, since the patient in the latter case may be completely overwhelmed by the typhoid toxins and no leucocytic reaction be possible. Kast and Gutig have recently shown in typhoid fever complicated by secondary infections, that the leucocyte count is much lower than in such infections which occurred alone and not as a complication of typhoid fever. Observations made by Longcope on the bone marrow in cases of typhoid fever have shown *that when the disease is complicated by a severe secondary infection there appears to be an actual inhibition of the formation of polymorphonuclear leucocytes in the bone marrow.* A wave of leucocytes has been described as reaching its maximum soon after perforation, then subsiding. A differential count has been claimed by some to be more reliable than a mere enumeration of the white cells, as a rule, as in commencing peritonitis there is a disproportionate increase in the polynuclear neutrophiles. Therefore, in drawing conclusions from any leucocyte count in typhoid fever, the normal leucopenia of this disease should be borne in **mind.**

Crile's observations on the increase of the blood pressure at the onset of peritonitis is an interesting one. This, however, I think has been long recognized as a clinical fact, but I have had no opportunity to employ this method of diagnosis in any of my cases.

DIFFERENTIAL DIAGNOSIS.

From what has previously been stated, it would appear that in a typical case of typhoid perforation, little difficulty would be experienced in making an accurate diagnosis. It so often happens, however, that the surgeon is called to see a case in consultation with the physician, and they see the case possibly for the first time and where it is impossible to obtain a satisfactory history. In this class of cases much difficulty has been experienced in elucidating what are the real factors to depend on in making an accurate diagnosis.

Monroe has expressed himself as having had difficulty in making a positive diagnosis where hemorrhage was concerned, finding it difficult to determine whether the true condition was responsible for many of the symptoms that present themselves. The collapse is likely to be the same in either case; yet hemorrhage is, as a rule, not attended with pain and absence of rigidity. The escape of blood from the bowel will soon determine the cause of the trouble. However, in one of my own cases both conditions existed, as was proven by laparotomy, the bleeding point ligated and the perforation in the bowel closed after the establishment of an artificial anus.

From appendicitis it may be impossible to make a positive differential diagnosis. In the latter, however, the pain is, as a rule, not so severe and the temperature shows no sudden drop, the pulse not so rapid and the faces not so strikingly changed, and there is also usually a history of previous attacks. In all cases, however, operation is indicated.

Peritonitis due to pelvic or ovarian disease can usually be eliminated by the history and a careful vaginal examination.

Affections of the gall bladder occur often during typhoid fever from infection of the typhoid bacilli finding its way into the gall bladder. This condition is not uncommon.

The pain in the region of the gall bladder, sometimes jaundice, without a fall of temperature, little shock, and the physical signs of tenderness, pain, rigidity and dullness, with a possible palpable mass in the region of the gall bladder, all aid in determining the character of the invasion.

Gastric and duodenal ulcers may perforate during an attack of typhoid fever. The local signs here are our chief aid in diagnosis, which will point to a perforation, with all the rapidly accompanying signs of interperitoneal irritation simulating a ruptured typhoid ulcer.

Iliac thrombo-phlebitis, with pain and swelling in the groin and along the course of the vein, will aid the careful observer in determining the character of the pain, as not that of perforation.

Suppurating mesentery glands or splenic infarcts may give rise to peritonitis during the course of this disease, and the symptoms are those of peritonitis pure and simple, and are not characteristic of typhoid perforation. When pain exists, the greatest care must be exercised to determine its origin if possible. The last two cases I saw presented all the typical signs of perforation, namely, intense pain, rigidity, with a hard, muscular abdomen and with a slightly anxious expression. Owing to the hard muscular abdomen the bladder could not be palpated; otherwise urine was passed with a fair degree of regularity every few hours, and a tentative diagnosis of perforation was made and permission for operation obtained, when, as if by magic, on the removal of 188 ounces of urine by catheter prior to operation, all the symptoms of typhoid perforation immediately subsided and all symptoms of interperitoneal irritation also disappeared. In the second case, all the symptoms were equally prominent and it was with difficulty that a diaphragmatic pleurisy was determined, but with the fixation of the side, etc., soon all the symptoms which were so characteristic of perforation disappeared.

PROGNOSIS.

The prognosis of intestinal perforation in typhoid fever is exceedingly grave, although there is no doubt that occasionally patients will recover where a perforation takes place in some quiet nook in the abdomen where nature closes it with a fold of omentum which rapidly seals in the offending perforation, thus permitting the case to go on to a favorable termination. This is proven by a specimen which is now in the museum of the Pennsylvania Hospital of a patient who died of some subsequent disease.

But recovery without operation is exceedingly rare and is hardly worth considering. Among 567 operations for typhoid perforation, to which I have reference, about 24 per cent. left the surgeon's hands well, leaving a mortality of 76 per cent. If from this number we were to exclude many cases in which the patient had really recovered from the operation, but died some weeks later, and not from the original typhoid perforation, this death rate would be materially reduced. But even this improvement, I am convinced, would be more than counterbalanced by the large number of fatal operations which have never been reported. Indeed, it seems to me that the surgeon who can cure one out of five of his patients is to be congratulated, since he is thereby sure that he has saved at least one individual from death, which would irretrievably have overtaken all the five if he had held his hands and refused the one hope offered by medical science of to-day.

It would seem as the result of my deductions from a large number of collected cases that the prognosis is more favorable in girls between the ages of 10 and 15, where the perforation occurred during the first week of the disease and when the constitution was still strong, or where the convalescence was pretty well established, and where the operation was performed immediately after the symptoms of perforation were recognized. It is certain that an early diagnosis, with prompt surgical intervention, is of prime importance if the desired results are to be attained.

OPERATION.

The operation for intestinal perforation is probably too familiar to everyone here to-day for me to take up too much of your time in discussing its technic at length. Yet, I think it is important to insist on performing it as soon as possible, and to shorten the time consumed in its performance to the utmost of our ability. I never wait for the shock to pass before opening the abdomen. The time which elapses from the first suspicious symptoms establishing the diagnosis, obtaining the consent of the patient and the family to operation, and in transporting the patient from the typhoid ward to the operating room, is all too great, and I look forward to the time when the consent for the operation will be given in all our large hospitals when the patient is first admitted. The surgeon who waits until the shock of perforation has passed will await the onset of diffuse peritonitis, with the death of his patient. The less time that elapses between the occurrence of the perforation and its repair by suture, the better it will be for the patient.

I have always employed general anesthesia in these operations and see no reason to change, although it has been found that the use of a local anesthetic is preferable in some cases. The operation usually lasts not more than 15 to 20 minutes from beginning to end, and the total unconsciousness on the part of the patient is more valuable by far in the rapid completion of the operation than any of the advantages, imaginary at best, which are claimed for the local anesthetic. It should not be forgotten that ether is a heart stimulant, and even a patient apparently moribund may improve so much under its administration as to render its employment justifiable. In other climates and higher altitudes I have no doubt that with care chloroform can be safely employed, but certainly in the middle and northern parts of the United States nothing is more satisfactory than ether.

In cases in which the diagnosis remained uncertain, but in which the symptoms did not ameliorate, I think an exploratory laparotomy is to be earnestly recommended. Experience shows that even if no perforations exist, most of these cases are nevertheless materially improved by the intervention; while in not one of the reported instances do I think the operation can be said to have in any way hastened death. I operated on two cases, in neither of which was there perforation found, but which went on to a favorable termination.

There are few surgeons at the present day who advocate other than the right iliac incision. Those who still employ the median incision must, I think, have a somewhat limited experience. The incision which I prefer is through the outer half of the right rectus muscle. It is straight, simple, direct and economical of time. The deep epigastric artery is not apt to be severed, with ordinary care and using the handle of the scalpel and not the blade to separate the muscular fibers. It is this route which gives direct access to our landmark, the cecum, and that portion of the gut which is most affected. It affords sufficient room for exploring nearly the whole abdomen and can be extended in either direction at need, and offers excellent drainage facilities.

When the peritoneal cavity is opened the cecum should immediately be located, when the vermiform appendage is at once recognized and can be removed if necessary. If the extravasation is free, no packs are required. If, however, peritonitis is fairly well circumscribed, the affected areas should be walled off with large pads. The ileum is next drawn into the wound and carefully examined. For this examination it is of very great advantage to have two pairs of eyes, as it passes rapidly through the surgeon's hands, one watching the upper and the other its lower surface. It is usually inadvisable to replace the gut at once on withdrawal, as this consumed valuable time which is better spent searching for the perforation until found. If there still appears to be reason to consider a perforation present, the eventrated parts should be re-examined, commencing at the highest part withdrawn and ending at the cecum, the coils being replaced as the return is made, but the highest coil being kept out of the belly until the others have been replaced as the starting point for another search, which should proceed upward along the ileum with like maneuvers, until there appears no further prospect of finding a perforation, and this probability decreases and the area of greater inflammation is left behind. If fecal extravasation is free, a medium or large-sized hole may be expected. If lymph abounds and clings to the bowel in patches, frequently beneath one of these patches will be found the pin-head lesion, as a dark spot occupying the middle of an intensely congested Peyer's patch.

As soon as the perforation is found it should be sutured and the toilet of the peritoneum should not be commenced until further soiling of it has been prevented. In about one in eight cases more than one perforation is present, and hence diligent search should be made of all inflamed areas and every spot threatening perforation should be investigated. Inversion of the perforation with Lembert's sutures of black silk is usually best done in the long axis of the bowel, as there is less risk of producing stenosis of its lumen. Sutures applied transversely to the bowel are, however, more prone to tear out as the intestinal coils tend to resume their normal convexity.

Excision of the ulcer is not only useless, but harmful, as it consumes unnecessary time and may cause hemorrhage. If the perforation is so large as to preclude suturing, an omental flap should be adjusted over the defect, or if this or some similar device fails, an artificial anus should be established. Excision of the affected bowel by an end-to-end anastomosis is too severe an operation to be undertaken, and in every instance reported where it has been performed has proved fatal. The formation of a fecal fistula, on the other hand, is easy of execution, being possible merely by the judicious disposition of gauze packs, and if it were not for the impossibility of adequately draining the peritoneum through a wound in which feces are constantly discharging, it might be a procedure to be highly recommended.

My preference is distinctly for suture of the preforation first, then for suture of the omental flap, and then, all else failing, the establishment of a fecal fistula.

The toilet of the peritoneum must next engage the attention of the surgeon, and is a matter much in dispute in cases of peritonitis from any cause. Where on opening the abdomen it is found to be filled with fluid and escaped feces, there is no doubt in my mind that thorough irrigation with hot saline solution is the most efficacious and rapid means of cleaning the abdominal cavity, and I am sure that if rightly done it offers the patient the best chances of recovery. However, in cases where there is little or no escape of intestinal contents, where lymph has been thrown rapidly over a small perforation, I think that often judicious dry sponging with gauze will be more efficacious, as there will be less tendency to distribute infected material over greater peritoneal areas. But in cases where the infective material is at all widely diffused, there is no doubt that thorough douching with hot saline solution is much the more rapid and efficacious means of removing the materius morbi.

To satisfactorily clean the abdomen by irrigation it is not sufficient merely to pour a half tumblerful of cleansing fluid into the abdominal wound and then mop it out again in an aimlesss manner. The surgeon should be provided with a large tube having a lumen of a half inch in diameter and with multiple perforations. A rubber tube and funnel should be adjusted to this. Through this funnel should be poured gallons of hot solutions, the quantity being more important than the quality, so long as it has a temperature not below 110. This tube is applied first to the pelvis, then to the right and left flanks respectively, and finally, both above and below the mesentery, the surgeon's left hand separating the coils of the intestine, as his right hand manipulates the tube. The funnel should be held two or three feet above the abdomen of the patient, and the irrigation should be continued until the fluid returns clear.

During the irrigation it has invariably been my experience that the patient's pulse improves. This is no doubt due in part to the temperature of the solution employed, but also, I think, is to be attributed to a direct distention of the vascular channels with the saline fluid.

When the surgeon is satisfied that the abdominal cavity is as clean as it can be made by this method, but not before, the tube may be withdrawn, but he should allow the remaining portion of the fluid which has already escaped to remain within the abdomen. Drainage is best maintained by large gauze wicks, placed in those portions of the abdomen where the fluid is wont to accumulate. Usually the pelvis, each loin, and the sutured area should each be drained by a separate large wick of gauze, and the gauze should remain in place from five to seven days at least. Too early removal of the drain is not only very painful to the patient, but renders the formation of a residual abscess much more likely.

The intravenous use of normal salt solution during the operation is one of the most valuable means we have for preventing shock and sustaining the patient during the first few hours after the operation. The greatest number of deaths after operation occur within the first twelve hours, and if by any means life can be sustained until this period is over, the chances of recovery are materially increased. If the administration of saline solution is to be continued after recovery from ether, it is best given by hypodermic or enteroclysis. A pint may be given through a high rectal tube every three or four hours, the fluid being allowed to absorb slowly.

As a rule it is preferable to have the head of the patient's bed elevated, thus favoring drainage from the pelvis along the tracts of gauze. No food should be given by the mouth until the third or fourth day, nourishment being maintained by nutrient enema. The quantity should be small, depending somewhat on the toleration of the rectum. When food is finally given by the mouth, it should be remembered that the patient still has typhoid fever, as well as a sutured area in the intestine, and it should be of the softest and blandest character.

CONCLUSIONS.

1. Perforation of the bowel in typhoid fever is a much more common condition than is generally supposed, being responsible for about one death in every three cases.

2. The most common time of perforation is between the fourteenth and twenty-first day of the disease, and occurs in all grades of severity, from the ambulatory to the hemorrhagic type, and does not seem to be any more common in the hemorrhagic than in the milder types of the disease.

3. The ileum is the most frequent site of perforation, in the majority of instances the perforation occurring within 12 to 18 inches of the ileocecal valve. The next most frequent sites of perforation are the appendix and the cecum.

4. In a large percentage of cases pain is present, although it may be transitory in character. In about one-half of the cases the onset is sudden, severe, and with increasing intensity, localizing itself in the region of the right iliac fossa.

5. Tenderness and rigidity are present to a certain extent in all cases. The latter symptom I regard as a most valuable sign, and it is never wanting except in patients with unusually large and pendulous abdomens.

6. When perforation is suspected the temperature should be taken every hour, as it is only in this way that definite conclusions can be drawn with regard to any marked variation in this symptom.

7. Distention is a late symptom of perforation, usually not making its appearance until some hours after the perforation has occurred. The obliteration of the liver dullness is not regarded as a reliable sign of perforation.

8. The study of the leucocytes is of little aid, although occasionally their increase may make you more positive of the diagnosis. The differential count is of no practical value.

9. Before a positive diagnosis is made, pain caused by a pleurisy, pneumonia, cholecystitis, acute gastrointestinal indigestion, iliac thrombosis, appendicitis, peritonitis, the passage of a renal calculus, distended urinary bladder, or even a hemorrhagic exudate into the abdominal muscles, must be carefully considered. Any of these conditions may cause symptoms similar to those caused by intestinal perforation.

10. Nature may occasionally close one or more perforations, but the only rational procedure where perforation occurs is surgical intervention. No case is too desperate for an attempt, as it has not infrequently been noted that the mild cases succumb and the more desperate ones recover.

11. In cases of doubt where the symptoms point to perforation, the safest procedure is to operate. As a rule, cases operated on and no perforation found seem rather to be benefited than otherwise by the operation.

12. When the diagnosis has been made, I know of no condition, except possibly that of hemorrhage, where speed in operating is so important a factor in securing success as it is in intestinal perforation. Everything should be carefully prepared beforehand and all conditions considered, so that when the knife is once taken in hand things may move with rapidity and without interference. In too many instances it is a race with

death and there are often anxious moments when it is questionable which will win, yet in only 5 reported cases has death occurred before the operation was completed. A death on the table is always a most distressing occurrence in surgery, but doubly so if the surgeon has in any way to blame himself for delays which might have been prevented by care and forethought.

DISCUSSION.

Dr. Lawrence Litchfield, Pittsburg, Pa., asked Dr. Harte if he made any blood-pressure records in these cases. Dr. Theodore Janeway has pointed out that the sphygmomanometer is a valuable means of differential diagnosis between hemorrhage and perforation in typhoid fever, particularly if a pressure chart has been kept previous to the emergency. The blood pressure is also at times an important guide in the treatment of these cases. Dr. Litchfield also said that he would like to know if Dr. Harte employs general or local anesthesia in these cases.

Dr. Charles A. Powers, Denver, said that in his part of the country such work as Dr. Harte's has stimulated physicians to be on the watch for typhoid perforations and has made it possible to recognize these lesions much earlier than formerly.

Dr. Morris Manges, New York, said that he reported 19 cases last year, and in only 3 was there a drop in temperature; in fact, in some cases it rose. He believes that sweating and rigidity are symptoms of considerable value. Dr. Manges thinks that too much attention is paid to percussing the spleen, and that if more attention were paid to the liver and less to the spleen it would be better. He believes that spontaneous recovery is possible. In cases in which there is no perforation, for some reason or other the subsequent course of the case is always improved by operation, and he believes it wise to give the patient the benefit of the operation.

Dr. Richard Harte stated, in reply to a question, that he has had no experience with blood pressure, but it is a well-known clnical fact that in peritonitis and in the pre-peritonitic stage there is a disposition for the blood pressure to increase. He has always been in the habit of using ether. Some of his colleagues, he said, have used cocain, but he thinks, on the whole, that a general anesthetic is much preferable, as the patient's condition usually improves under the anesthetic. In closing the ulcer he uses fine black silk mattress sutures placed parallel to the long axis of the bowel. If the ulcer is very large, sometimes in order to close it stitches will have to be inserted in the reverse way; this has a tendency to shorten the bowel and to make the stitches more liable to tear out. If the condition is very bad he thinks it is safer to establish an artificial anus. There is nothing whatever to be gained by excising the ulcer. He feels confident that in all cases if the temperature is carefully and frequently recorded a distinct fall will be observed, which will assist materially in making a diagnosis. He expressed himself as greatly indebted to the courtesy of his medical colleagues for having allowed him to study their bad typhoid cases with them. This is of great advantage, since these cases so often pass from the hands of the physician to the care of the surgeon, and if the surgeon has been in consultation he may recognize changes which are likely to occur and is thus in a much better position to recognize them when they do occur than if he is seeing the case for the first time.

Consciousness and Its Degrees.—At the recent International Congress of Psychology Dr. Paul Sollier said that consciousness is not an autonomous primordial or independent phenomenon that can be isolated, that has an action proper to itself acting on other psychologic manifestations. There is no consciousness outside of cerebral activity. Consciousness is not even an epiphenomenon, as it exists even when we do not see its manifestations. If every cerebral center, taken individually, contributes to the production of consciousness, it may be said that there exists an indefinite fragmentation of consciousness—according to the number of cerebral centers that are brought into play.—*Journal of Mental Pathology.*

DELAYED UNION AND UNUNITED FRACTURES.*

CASPAR W. SHARPLES, M.D.
SEATTLE, WASH.

Norris has made general and elaborate classifications of these conditions, which are, in substance, as follows:

Class 1.—Delayed union, callus forms and union is not rendered complete by ossification.

Class 2.—Entire want of union, the ends of the bones are diminished in size, there is motion between the fragments and the limit of this motion is usually small.

Class 3.—With fragments small, rounded off, tapering and bound together by fibrous bands.

Class 4.—Pseudarthrosis; a dense capsule seems to form around the ends of the bones; on opening this a fluid is found resembling synovial fluid. The ends are eburnated.

By referring to numerous authors along about the fifties, I found a few notes in regard to the causation of ununited fractures. The principal ones correspond very clearly to our present ideas, and I am sure that this quotation from Velpeau places him and his opinion on the causes of ununited fractures among many surgeons of to-day. It is this: "If the fracture, whatever may have been the primitive cause, shall have become reduced to an effect already local and shall have not united, partly because its two fragments have cicatrized separately."

He also quotes the following facts from the "Cyclopedia of the Practice of Surgeons," published about that time, in regard to the result of treatment in these certain cases, which I insert at this point simply as a matter of history.

There were 150 cases recorded, of which 46 were treated with the seton, 36 of which were cured, 3 were partially cured, 5 received no benefit, and 2 died. There were 38 in which resection was tried, 24 were cured, there was 1 partially cured, 7 received no benefit, and 6 died. There were 36 cases in which pressure and rest were employed, 29 were cured, 1 was partially cured, and 6 received no benefit. There were 8 in which caustic was employed, 6 were cured, and 2 received no benefit. There were 11 cases in which friction was employed, and 11 were cured. Eleven cases were treated by the use of iodin injections, hot iron and amputation. Seven were cured, 1 received no benefit, 2 died and 1 remains uncertain.

It is also interesting to note that in 1760 a surgeon by the name of White operated on an ununited fracture of the humerus, in which he parted the two ends of the bone, sawed them off and placed the freshened ends in apposition; and also operated on an ununited fracture of the tibia, in this, however, merely exsecting the upper end, and in both cases obtained perfect results.

I am sure that these results must seem more or less remarkable to us at the present day, with our extreme ideas of asepsis and the constant fear that exists in our minds lest pus should form in our wounds when operating for these conditions, and our willingness to attribute a failure under these conditions to the presence of such an infection.

Velpeau, in his conclusion in regard to ununited fractures, explains it as his opinion that the seton will only succeed in these cases where the ends of the bone are in actual contact or nearly so, and that in all these cases in which the ends of the bones are not in contact there is no operation that promises better results than resection.

---

* Read in the Section on Surgery and Anatomy of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

In the American appendix to this treatise of Velpeau, Dr. Blackman has given the details of an operation which I believe was devised by Professor Brainard, of Chicago; it is probably our present drilling operation, and in 1854 Brainard published descriptions of seven cases in which six operations had been successful. This drilling was supposed to be of use by bringing surfaces of bone freshened by the operation into apposition.

Local conditions probably have more to do with ununited fractures than do constitutional states. Though just what these local conditions may be, it is not always easy to tell. For a long time the prevailing opinion was that ununited fractures depend very largely on some interposing substance which interfered with repair, such as muscles, tendons, arteries, nerves and fascia. The prevailing idea of such an interposition, no doubt, depends on one or two reported cases of fracture, in which a bundle of muscular tissue had become incarcerated between the fragments, and particularly one case in which there was a fracture of the clavicle that was firmly united, but in which the callus had been thrown out over and around the muscle so that there was a fenestration through which the muscular fibers passed. The possibility of muscular fibers being interposed is very materially lessened on account of the natural contractility of the muscles. We have all noticed in amputation that when the muscular fibers are severed they retract; we also have noticed when, as the result of the injury, a muscle has been ruptured, that usually if the rupture involves sufficient bundles of fibers, retraction occurs so that a depression may be felt, which depression, of course, depends on the extent of the injury and the length of the muscle, as well as its tonicity.

It has also been noticed that, in an injury in which the tendons have been severed, there is a very decided retraction which at times is very difficult to overcome. In the majority of instances of fracture, the muscle itself is not extensively lacerated, though probably there are very few fractures in which some injury does not occur to the surrounding muscular tissues. Also in fracture there is seen a spasmodic condition of the muscles depending on two acts: First, on Nature's effort to fix the ends of the bone to avoid motion between the proximal ends of the fragments, also to save the patient from pain, and, second, on the irritation of the ends of the fragments of the bone in the muscular tissues—itself a sufficient cause of this spasmodic state of the muscles. By this action lacerated muscular fibers would, no doubt, be pulled from between the ends of the bone should they have become incarcerated in the place of being allowed to remain in their false position, and hence later to prevent union. So, also, would the treatment, which should be employed in every case of fracture, that is to overcome the strength of the muscle so far as possible by extension in order to enable us properly to reduce the fracture, tend to withdraw all fragments of muscles that might become incarcerated. This, it strikes me, would apply both to the lacerated muscles and to the muscular fibers that were not lacerated, and I believe, in consideration of the above facts, that muscular fibers and tendons only rarely play any part in the causation of ununited fractures. Such instances as may be demonstrated, either by operation or postmortem, to have occurred, are rather only medical curiosities, and many times I fear that the fibrous tissue that has been thrown out to complete the pseudarthrosis has been confounded, at the time of operation, with the muscular tissue. I know that this idea has been advanced more than once.

Considering the subject of ununited fractures, it, of course, is necessary that we have some idea of the method of repair of ordinary fractures, in which the periosteum is usually lacerated, but not often torn apart. Its fragments are separated from the bone over a greater or less area and theoretically, at any rate, bands of the periosteum after the injury will, no doubt, maintain the continuity of the membrane. There is also a hematoma of varying amount, depending on the character of the bone that is injured and also on the amount of injury to the surrounding bones. Part of this blood is absorbed and part of it finds its way between the layers of muscles and fasciæ to the surface and is thus removed from around the seat of injury.

The process of repair begins simply by granulations spreading from the shreds or non-lacerated portions of the periosteum and by filling the space between the ends of the bone, which goes to form the provisional callus, completely enveloping the seat of injury. Its shape and size and the relation of the bone ends depend on the amount of displacement, so that the callus is formed gradually by a thickening of the periosteum and granulations from the soft parts of the bone ends and the marrow (which is slower in forming) on the thickness of the periosteum and on the granulations from the soft parts of the bone ends.

The major part of the callus, the periosteal part, first becomes cartilaginous and then bony. That coming from the marrow becomes bone directly without the intervention of callus. The slowest part of the callus to develop is that between the bone ends, inasmuch as the circulation is here very poor and because a certain amount of the thin shell along the surface of the bone has been deprived of its nutrition and has to be absorbed, and this portion of the callus only forms from bone granulation. The final stage of this bone formation occurs in the absorption of the exuberant callus. The process is really incomplete until months after the reception of the injury. From the very nature of events it must be granted that compound fractures are more liable to be followed by variation in the normal process of repair than are simple fractures, for there is more disturbance of the surrounding tissues, and such local conditions must of necessity have their effect on the other bones.

In compound fractures, the violence is, of course, more severe. The periosteum is often times completely lacerated and destroyed, in some cases even sloughing off as a direct result of the injury. The violence done the soft tissues by protruding bone may so destroy the vitality of the tissues that there is an increase of possibility of infection, and it may be sufficiently severe to cause sloughing of the soft parts. Since we have seen that the periosteum plays such an important part in the primary, or in point of time first, location of granulation tissue, it is but fair to conclude that those injuries that cause extensive disturbance and retraction of the normal relation of the periosteum would be less liable to be followed by good results, and this the more so if apposition could not be or were not maintained.

Compound fractures are attended with hemorrhage, as a rule, and this probably acts on the part to delay the formation of granulations which we have seen are so essential to callus formation. I recall one or two instances in which a hematoma had existed for some time, had been evacuated, under other conditions, and in neither of these was there any evidence of the formation of granulation.

A colleague, Dr. Yocum, of Tacoma, called my attention to the fact that all cases of ununited fractures that he had operated on and drained had done well, and that all cases in which drainage had not been used had done poorly, and on account of this he advocates the use of drainage more frequently. In cases that had come to operation, and by way of emphasis of the correctness of this method of procedure, he had made another observation, which was this: Two cases had been operated on without drainage, with the result that both were failures, but on doing a second operation in each case drainage had been used in both with good results. The drainage used in late operations might act as the seton did years ago. Hemorrhage may also act as a complication on account of its amount, producing pressure enough, unless the hematoma would rapidly absorb, to lower the vitality of the surrounding parts.

In compound fractures it is, of course, desirable not to disturb the parts to any greater extent than is absolutely necessary to enable us to cleanse the wound and to endeavor to make proper apposition of the fragments, and that, of course, can not always be done in some cases, nor can we aid much in the relation of the periosteum to the ends of the bone. Malpositions often cause delay in union, or in others lack of union. It is wonderful what measures Nature takes to provide for and to overcome our many imperfections and lack of skill in providing for union of fractures. None are more wonderful than can be seen in many cases of so-called vicious union where only some small area of the fractured surfaces have been approximated and where the overlapping ends of the bone are firmly united to one another to produce a stiff limb; but it is not always that Nature can throw out enough callus to cover two ends widely separated. It is not an uncommon condition to find the ends of the bones fastened to one another by fibrous tissue and a false joint thus formed, showing more or less motion. At other times the bones may be separated latterly one-half inch or so from one another with overlapping ends. One case that I had the opportunity of examining with the *x*-ray very clearly showed this condition. In it had been a large amount of hemorrhage and, of course, much swelling, and there remains the possibility that the ends of the bones may never have been approximated, in which case Nature never had a fair opportunity to provide callus. The operation showed simply fibrous tissue and the ends of the bones reduced in size. In about three months after the operation there was a small amount of callus being thrown out round one bone and none around the second. Two or three years ago I saw a fracture that had occurred five weeks before, where great violence had been done both to the lower part of the tibia and fibula and to the ankle by being crushed between two logs and, as subsequently proved, there was one fracture in the fibula and two in the tibia, though only one was diagnosed until after amputation. Osteomyelitis started in the ankle bones and in the lower part of the tibia, and there was during the progress of this an evidence of non-union. An operation was done to remove the diseased bone from the ankle and the tibia, followed in a few weeks by the second operation, with consent to amputate if found desirable and agreed to by the consultants, but it was not done at this time on account of the inability of three of us to agree. The pain, fever, chills and sweats returned, and in about two weeks more amputation was done. There never seemed to have been any particular effort at repair excepting in one spicule. This is the only case of the kind that I have seen, and I have not seen mention of another one, but I do not see how the presence of such an extensive disease as existed in this case could have failed to produce delay.

Among other causes for ununited fractures is said to be tight bandaging and the use of the leg too soon after the injury. In all cases in which there has been an injury to the nervous supply there is likely to be delayed union. In no case in which a fracture has occurred in the bone at the seat of a malignant disease is union to be looked for, but should a fracture occur in a subject who is suffering from cancer in some other location, the bones being brittle, union should be expected. Pregnancy and lactation have been assigned as causes of delayed union. Likewise syphilis, and especially so during the chancer period.

After all is said and done, the practical point in these cases is the question what shall be done to make useful limbs for our patients. Medical treatment of ununited fractures has assumed many forms, but it is chiefly dependent on the administration of tonics and the use of such hygienic measures as would tend to improve the general condition of the patient. It, of course, can not be denied that in this state, or in any other below par, the lowered general vitality of the patient decreases the general tone of the body to such an extent that many of the normal functions are not being performed as they should be, so that it would hardly be anticipated that any special call of an unusual nature on the functions of the body for the repair of an injury would be responded to in as satisfactory a manner as it would be with the whole condition up to normal. Otherwise it does not strike me that there is any good to be derived from filling the patient up with medicine under ordinary circumstances. There have been some cases reported, however, in which the administration of thyroid extract is supposed to be of value. This report is based undoubtedly on but few observations which have been made in cases of delayed union, also on a few cases in which there was an absence of a part of the thyroid gland or cases in which that function was interfered with, in which the administration of this material seemed to be of value, and possibly it would also be suggested by the effect of the administration on the gland in producing an increase in the growth of the bones in cretinism. One case is reported in which union was delayed for eighty days, and after the use of thyroid extract, five or six tablets a day, of a grain and a half each, union began and a useful limb resulted. It is not unusual, however, to see cases in which union is delayed such a length of time and a firm limb follow without the administration of any medicine. With its use I have only had one experience, and the result of that was negative. In all cases in which there is a specific infection, treatment for that condition is undoubtedly advisable.

Next to medicinal treatment on the basis of simplicity is to put on the limb a good strong plaster cast and set the patient out with a pair of crutches, with the instructions that he should use his limb, that is, putting a small amount of his weight on it as he walks around from time to time. In many cases this is associated with more or less pain at first, but the patient gradually becomes accustomed to it, so that there is very little inconvenience.

I at present have under observation a patient who had a compound comminuted fracture of both bones of the leg, over eighteen months ago, who is walking around without any support other than a cane. The bones have slipped by one another; and he says that it is with very little inconvenience or pain that he travels. I have seen a number of patients with delayed union, the length of time which has elapsed since the injury varying from two to five months, that have made good recoveries simply by this treatment, and I believe that before any operating measure of any kind is undertaken that this method of treatment should be adopted and carried out for a period of at least three months, in the hopes that the reactionary effect of the irritation produced by the walking may cause to be thrown out, some inflammatory material or granulation tissue on the surrounding parts, or the periosteum, or between the ends of the bones, or from the medulla that would ultimately be formed into substantial bone. Should this procedure fail, then some operative treatment must be adopted. The simplest of all that is recommended is rubbing the ends of the bones together, but, of course, that would be of no use after the patient had walked around for a number of months, since the bones have undoubtedly had sufficient rubbing. In a case in which the preceding form of treatment has not been adopted, however, this method of making friction might be of use, and this should be followed by the application of a firm cast. The next simplest operation is that of drilling the ends of the bones, which may be done subcutaneously or through an open incision, and this to be followed in turn by fixation in a cast, or by allowing the patient to go around with crutches after fixation, hoping that as before it will excite the formation of a callus and new bone.

The open incision is probably better in some ways, since it gives the surgeon an opportunity to protect the underlying tissues from injury by the drill point, but since it is a fact that ununited fractures more frequently follow compound fractures, I believe that if it were possible to avoid an open incision, it should be done. In many cases it seems that bone operations are necessary, and after all the simpler means have failed, this method should be resorted to, and just exactly the procedures that should be adopted depends on the local conditions. If necrosis exists, all such bone must be removed, and more or less resection becomes a part of the operation so as to bring the fragments into good apposition. One case that I was asked by a colleague to operate on had necrosis of the tibia and of one end of the fibula; all this necrosis was removed, the bones materially shortened and united as an oblique fracture. Infection occurred, but a fairly good result was obtained, and during the progress of this case the wound was treated through a fenestration in the cast. The leg turned in the cast so that the foot described an arc of 90 degrees, the toes pointing inward, and a new cast, after a period of thirty-six hours, was applied, extending above the knee; this held the foot firmly. A good solid leg resulted which he is now using for all practical purposes. Almost any method of treating the ends of the bones can be used that would bring healthy bone tissues in each fragment into apposition. The most common one is to unite the ends of the bones obliquely and use some means of securing fixation.

In some cases, in order to secure this perfect fixation, it might be possible to make a shoulder in each fragment, and so with the two ends of the bone overlapping, as carpenters arrange their heavy timbers, and through this overlapping part to insert some material to maintain the position, either bone pegs, ivory pegs, wire or metal pegs. Silver wire is what I have been accustomed to use. Two or three times it has had to be removed on account of the irritation that it has caused and an existing sinus. I doubt also if silver wire or any more flexible material would produce absolute fixation by itself. Screws and various bracketed metal braces fixing the bone have been devised.

Dr. Leonard Freeman has recently reported a case in which an ununited fracture of the neck of the femur has been treated by fixation by a screw with good results. Parkhill's apparatus is probably the most commonly used, but the results seem to be the same whether the simplest method of fixation or the most complicated method is used. All of these patients can not recover, no matter how much care and attention may be given to them, no more than we can tell the cause of all ununited fractures.

DISCUSSION.

Dr. Martin, New Orleans, is convinced that many ununited fractures are caused through improper reduction, or the interposition of soft tissues. After the physician has reduced the fracture he should try to get crepitus, as he will then know that there is bony apposition. Wire does not fix the bones. It is impossible to bring the bony ends in apposition sufficiently tight for wire to hold them there. There will always be a certain amount of union. Dr. Martin has been using a wire staple, made of piano wire. This is very stiff and fixes the ends absolutely. He has very rarely had to remove them, but if suppuration occurs this is a difficult matter. He believes that drainage is necessary when one has to sew the ends of the bones. In any event it is always a safe thing. Dr. Martin operated in one case recently in which the injury was so superficial that he had no trouble and got a perfect result.

Dr. Thomas W. Huntington, San Francisco, said that, with an extensive experience extending over a period of 25 years, he does not recall a case in which delayed union could not be definitely traced to faulty adjustment and malposition. This opinion is based on a large number of cases in which he has operated for the relief of this unfortunate condition. Interposition of foreign material seems to him a consequence of malposition rather than a direct cause of non-union. The point which should be uppermost in the mind of the surgeon is the correct adjustment of the fracture early in its history. In this particular undertaking the aid of the *x*-ray should be invoked as often as possible, and from time to time after adjustment the status of the fracture should be checked up by the aid of the *x*-ray during the course of treatment. It is not uncommon in his experience to find a week after a careful adjustment that displacement has occurred. This happens particularly in fractures of the shaft of the femur in which the adductors displace the lower fragment internally and the opposite muscles acting on the upper fragment displace it externally. After an honest effort for the correction of the deformity by ordinary means, it has been Dr. Huntington's practice to offer the patient a better result by the use of some artificial means such as wire suture. The maintenance of permanent appositon without such interference is often times extremely difficult if not absolutely impossible.

Dr. Harry M. Sherman, San Francisco, said that no one has referred to rupture of the nutrient artery of a bone as a cause of delayed union or non-union. Fractures occur at all ages. In a child so injured, when the nutrient artery is torn off, it is possible to have non-union, and union never occurs when this takes place. The lower fragment is deprived of blood in sufficient quantity and atrophies, and one can thrust a scalpel into it; it is so fragile and soft, while the upper fragment is dense and bone-like. Dr. Sherman has seen this occur in cases in which he has operated to correct a deformity of the tibia, and the line of the section of the bone happened to be across the course of the nutrient artery. Reposition in these cases has never been very difficult to secure, and when the fragments were put in place he felt sure there was no interposition of soft tissue. This tearing off of the nutrient artery can occur in an adult, as well as in a child, and then the upper fragment alone makes effort at repair, the lower fragment does not. Surgeons must count the rupture of the nutrient artery as one of the most important causes of delayed union and of non-union. So far as crepitus is concerned, as testifying to the fact that bone is against bone, Dr. Sherman thinks it should be satisfactory to most of surgeons. He does not mean to detract from the value of the *x*-ray, but surgeons can not have *x*-rays in patients' homes as well as in their offices. The *x*-ray should be used to prove or disprove a diagnosis that has been made by the usual clinical methods. A man who does not make an effort to reset his fracture by the old methods, is robbing himself of all his old intelligence. Surgeons must not dull the edges of their senses by the *x*-ray, as it is said the edges of knives were dulled by the discovery of ether.

Dr. J. S. Hunkin, San Francisco, declared that the important point is securing immobility at the seat of injury. The usual failure is not in getting the ends of the bone in apposition, but in making the splint long enough and tight enough to hold them there. Surgeons have been led astray by the idea that swelling would promptly follow if the splint were tightly applied. As a fact, swelling does not take place, provided pressure is evenly graduated, regardless of the tightness. Dr. Hunkin puts all fractures of long bones in a tight, snug-fitting plaster of Paris splint, and he does not see non-union. The splint as usually made is not long enough to secure sufficient leverage. Long leverage and close application spells immobility, and immobility means union.

Dr. W. J. Means, Columbus, Ohio expressed his surprise at the emphasis placed by Dr. Sharples on the matter of drainage in the operative treatment. It has been Dr. Means' experience that better results follow in cases in which drainage is not used. The question of ambulation is confined chiefly, in his judgment, to cases of transverse fracture in which there is good apposition of the fragments. When the question is only a matter of delayed union due to malnutrition, ambulation produces an irritation that will aid very much toward normal repair. In cases in which the fragments are not in apposition or can be forced out of position, ambulation is of questionable utility. He is fully convinced from an extended experience that the main cause of non-union is a lack of proper apposition. Therefore, the open method of treatment is the proper one in a majority of cases. He suggested that the open treatment should be used in all fractures in which proper apposition of the fragments can not be maintained, and that the treatment should not be delayed for weeks and months to ascertain how much Nature may do toward securing permanent union. This method will not only avoid vicious union, but will save much time to the patient. The method of uniting fragments can not be uniform. It depends on the individual case and the conditions with which one has to deal. One of the happiest results that he has had in several years was in a recent case of non-union of a fractured femur, in which operation was done after a period of ten weeks. He found the fragments over-riding; they were placed in apposition and held there by a notch in the upper fragment and a corresponding projection on the lower fragment. The periosteum was sutured over the ends of the fragments with catgut, and the incision was closed without drainage. The leg was then placed on a double inclined plane without extension. The patient made an uninterrupted recovery, and left the hospital seven weeks later with a perfect recovery. Dr. Means believes that if possible non-absorbable material should be avoided in bone operations. The method he suggests is applicable, he thinks, to a large number of cases of fracture of the long bones.

Dr. C. W. Sharples demonstrated his method on the blackboard. He has used silver wire and has obtained good results, but he is sure silver wire does not secure the best apposition. Wherever the periosteum can be saved it should be done. Whenever it is possible to do so, he believes that the best method is to cut a shoulder on each fragment and to fasten these together with some sort of pegs. Surgeons will thus come nearer getting good results than by any other method. More raw surface will be brought into apposition. Fibrous tissue intervening between the ends of the bones and causing ununited fracture is nothing more than an attempt to heal the parts. This is a part of the formation of an ununited fracture. In fractures of the tibia, one needs very perfect apposition. Many cases of fracture have not united well, and yet the result has not been considered vicious union. The part that the nutrient artery plays is important. Dr. Sharples believes that he has seen a case of ununited fracture due entirely to an injury of the nutrient artery.

A PHILIPPINE FEVER.[*]

H. D. BLOOMBERGH, M.D.
AND
J. MORGAN COFFIN, M.D.
First Lieutenants and Assistant Surgeons, U. S. Army.
MANILA, P. I.

We wish to place on record two cases of an infectious disease, occurring in the Philippine Islands, which is characterized by a remittent fever of short duration and the presence in the blood of a motile hemocytozoon. These cases will be of particular interest to medical officers of the U. S. Army in the Philippines, where yearly numerous cases are recorded in the sick and wounded reports from the various posts as "fever, type undetermined," and this in spite of the fact that careful microscopic examinations are almost universal and that the resources of the Division Hospital laboratory are easily accessible for serum diagnoses.

Case 1.—J. R., private, First Cavalry, Hospital Corps, U. S. Army, admitted to hospital Aug. 1, 1905.

Family History.—Father died of diabetes, mother of cerebral hemorrhage. No brothers or sisters.

Personal History.—Had diseases of childhood. No pneumonia, typhoid, dysentery, malaria or rheumatism. The patient states that during his two years of service in the Philippines he has always been healthy and well. He is 25 years old.

Present Illness.—No premonitory symptoms. Was sick one day previous to admission. Had slight chill, followed by fever, but no sweat. Fever continued to time of admission. Slight headache, no pains in back and limbs.

Condition on Admission.—The patient complained of fever and general malaise. He looked sick. He suffered no actual pain. No cough, no expectoration, no dyspnea, no vertigo, no headache, no cardiac palpitation, no nausea and no vomiting. Appetite was poor and bowels were constipated. Patient stated that he was passing normal amount of urine.

Physical Examination.—The patient was a well-nourished white man. Skin in good condition. There was no rash present. Face was flushed and conjunctivæ injected. The lungs were clear throughout. Heart sounds were clear and of good quality. Area of dullness, lower border third rib, left parasternal line, to the apex beat, which is visible and palpable in the fifth interspace mid-clavicular line. The liver is not enlarged. The spleen is found between the ninth and eleventh ribs and is not palpable. No tenderness in the abdomen, no masses, no distension.

The laboratory reports show a negative diazo reaction, a faint trace of albumin and no sugar and casts in the urine. The red blood count was 5,344,000, the white blood count was 5,200, the hemoglobin 100 per cent. and the differential unimportant. The blood culture and an inoculation into a monkey were followed by negative results.

After the patient had been in the hospital for three days with a fever suggesting typhoid infection, the fever fell by crisis, whether as a result of the hypodermatic administration of quinin or not we can not say. On August 3 the patient vomited a small amount of greenish fluid, and on the 4th he had a sweat for the first time, which was of slight duration and amount.

Without any complications the patient passed through a rapid and uneventful convalescence and was discharged. (Chart of Case 1).

The interesting point in the case was the finding in the red blood cell of a hemocytozoon entirely different from the hemameba of Laveran. It was lying in red blood cell which was uncrenated and free of vacuoles. The cell was of normal size and color. The organism was approximately 2.5 microns long and 1 micron broad, was unpigmented and refractive to the same degree as the malarial parasite. By frequent and irregular alternate contraction and lengthening of the longitudinal and transverse diameters the parasite varied in shape between an ovoid and spindle form and at times what was apparently the underlying hemoglobin became visible. After being observed for several hours it became motionless and with the enclosed hemoglobin appeared as an oval-shaped body. In specimens kept over night a few narrow, ring-shaped bodies were found.

---

[*] From the Wards and Laboratory of the Division Hospital, Manila, P. I.

Of still greater interest is the motility of these organisms. This was of two kinds. The first depended on a revolution on either one of its two axes. When revolving on its transverse axis, it appears as a refractive dot or as described above. When revolving on its longitudinal axis, it appears as described above or as a slightly curved rod with slightly bulging ends. The change in revolution from one axis to the other was continual and the rapidity was very great.

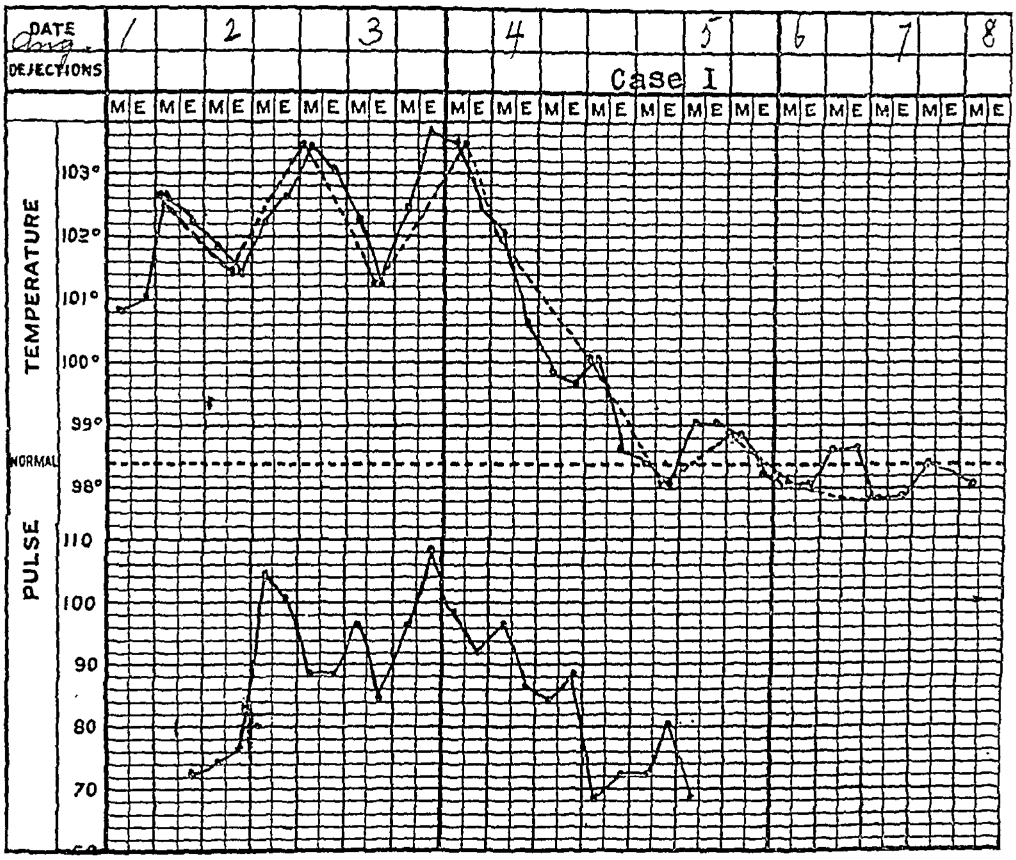

Chart 1.

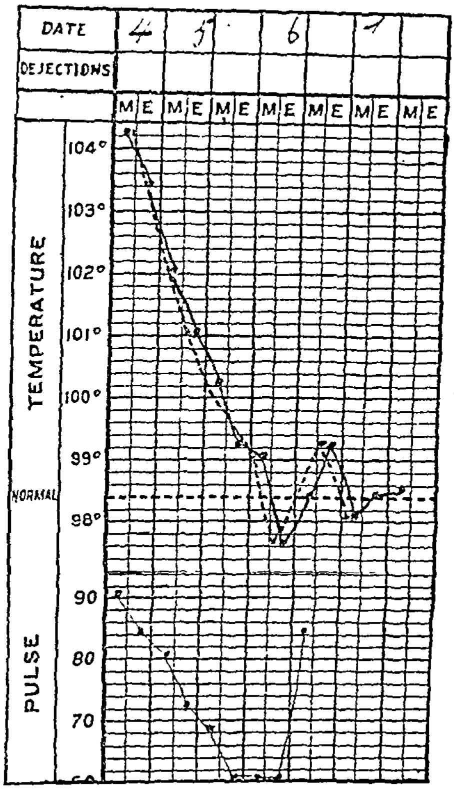

Chart 2.

The second form of motility is the movement of the organism in relation to the containing cell. The organism would not remain stationary in the cell, but moved rapidly from one position to another, while maintaining at the same time its independent motility.

Case 2 is similar to Case 1 in most respects and is reported inasmuch as the temperature fell by crisis without the administration of quinin.

Case 2.—The patient gave a history of three days' illness, which started with vague chilly sensations, but no rigor, fever but no sweating (Chart 2). He suffered with severe muscular pains. The crisis was followed by profuse sweat. All signs and symptoms in this case improved immediately and the patient was discharged a few days later in normal health. The laboratory examination showed a slight trace of albumin and unimportant findings in other excreta.

On the day following admission the blood showed a hemacytozoon similar in many respects to the one found in the preceding case, but smaller, less motile and less refractive.

Inasmuch as the Division Hospital receives a great majority of its patients transferred from various post hospitals, we have seen very few of these cases of fever of short duration, but we believe from what we have learned from surgeons serving in certain posts that there is an unknown fever in the Philippines which lasts between three and ten days in which no malarial parasites are found and which may recover without the use of quinin. The cases which we have reported appear to be similar to those that have been described to us, and if the diseases are identical the reason that the parasite has not been generally recognized is probably on account of the fact that it is found in very small numbers in the blood, no more than one parasite being found in one coverslip preparation, and it being frequently necessary to examine three or more preparations before the parasite is discovered. We have been unable to stain the organism, in spite of the fact that we have used the various approved methods for staining protozoa, including a Wright stain that readily stains chromatin, but we believed that possibly our attempts were in vain because of the fact that our coverslips did not contain the parasite.

We have described hitherto only the motile parasite. We have, however, found other resting bodies described by Cropper[1] in detail and also noted by First Lieutenant H. M. Smith,[2] Assistant Surgeon, U. S. Army, but these resting bodies are so difficult to distinguish from artefacts and occur so frequently in the blood of residents in the tropics that at present we are unwilling to recognize them as parasites.

Regarding the motile hemocytozoon, so far as we know, Smith was the first to describe it. Although his cases were included under the heading of estivo-autumnal malaria, he states that the form of the parasite was so peculiar as to make it difficult to decide whether it was really a malarial parasite or some other organism entirely distinct.

---

[1] Journal of Tropical Medicine, May 1, 1905.
[2] Surgeon General's Annual Report, 1904.

We have attempted so far only to describe a disease and an organism associated with it in the blood. On account of the absence of pigment and ameboid movement and the fact that we could notice no growth nor find any extracellular forms, we believe that this parasite does not belong to the same genus (*Hæmamœba*) to which the malarial plasmodium belongs.

Special Article

IMMUNITY.

CHAPTER XXIX.

LEPROSY.

Course of Extension.

Leprosy existed in Egypt in prehistoric times and extended to another land only when intercourse was established between the two countries. It reached Greece at about 345 B. C., Italy in the first century before Christ, and from the latter country extended to Germany, France and Spain. Crusaders returning from the Orient also brought back the disease in later times and eventually all Europe was infected. Leprosy is known to have existed in Great Britain in the tenth century, and from that country it was carried to Iceland and Greenland. From Germany it extended to the Scandinavian countries, and from the latter to Finland and Russia. It also reached Russia from the South and East, and in the South it was at one time called the Crimean disease. The West Indies and South America probably were infected from Spain, and through these channels the disease was carried to the southern states. The leprosy of the western states seems to have been imported by Norwegian immigrants chiefly. In 1902 the United States leprosy commission found 278 cases in this country. One hundred and eighty-six of these individuals probably contracted the disease in this country, 120 were born in foreign countries and 145 were native born. The disease also extended around the globe in the opposite direction, reaching China, Japan and the East Indian islands from India. The Sandwich Islands became infected in the nineteenth century.

The contagiousness of the disease appears to have been recognized at a very early period. In 636 A. D. leprosy houses were instituted in Italy and other countries, and the practice of segregating lepers soon became general. The hospitals were called Lazarus houses in middle Europe and St. George houses in Scandinavian countries. Pipin and Charles the Great declared marriage between lepers illegal. The rapid disappearance of leprosy in middle Europe during the sixteenth century is ascribed largely to the segregation of the patients.

Bacillus of Leprosy.

In 1872 Hansen announced that small rods, sometimes intracellular and sometimes free, were to be found constantly in teased preparations of leprous tissue. These rods, leprosy bacilli, are now universally recognized as the cause of the disease, and in 1879 they were stained by Neisser and a year later by Hansen. The organism is non-motile, has about the dimensions of the tubercle bacillus, the same staining reactions, and frequently shows a beaded appearance (degeneration forms (?)). It is said to take up dyes more readily than the tubercle bacillus, but the difference is not so great as to be distinctive. It stains by Gram's method.

Success in cultivating the bacillus has been reported a number of times, but the researches of others have failed to confirm these successes. Up to the present time it is probable that the organism has not been made to grow in artificial media. The resemblance of the bacillus to other acid-fast organisms, which are not pathogenic for animals, and the nonsusceptibility of experiment animals to leprosy, are conditions which render very difficult the identification of a culture as that of the leprosy bacillus. Nicolli is said to have produced leprous nodules in monkeys by inoculating them with diseased tissue.

Dissemination.

So far as known the organism has no natural existence outside the human body, and it is disseminated only by the secretions of the diseased. It is discharged chiefly through the secretions of the nose and the upper respiratory passages, the surfaces of which are so commonly the seat of leprous ulcers, and also through ulcerating lesions of the skin. Expectoration, sneezing and coughing have approximately the same significance for the dissemination of leprosy bacilli as of tubercle bacilli. Infected droplets of sputum may be emitted by forcible speaking. It is stated that the organisms found in the sputum and nasal secretions appear to be largely degenerated, a condition which may lessen the infectiousness of these substances.

Transmission.

The infectiousness of the leprosy bacillus is of a low character. "Epidemiologic experience teaches that infection occurs only through intimate and prolonged association with the diseased, in which doubtless uncleanliness plays a very important rôle" (Gotschlich). A leprous husband eventually infects his wife, and the children of lepers commonly develop the disease early in life. The high percentage of leprosy which is noted among the laundresses of infected localities indicates that the disease may also be transmitted by indirect contact. Gotschlich throws some doubt on the importance of dust infection since so many of the bacilli found in sputum appear to be degenerated. Nothing is known of the resistance and viability of the organism outside the body.

Infection Atria.

On account of the early appearance and almost constant occurrence of leprous lesions in the nasal passages Stricker believes that the latter constitute the chief infection atrium; of this Hansen is not positive. Nasal ulcers may be present in latent or apparently healed cases. Kolle cites a case showing extensive involvement of the spleen and liver in which the intestinal tract was considered the infection atrium. In some instances in which the disease is first noted in the feet, the organisms are supposed to gain entrance with infected soil through abrasions in the skin. According to Cornil and Babès, infection may take place through the hair follicles and sebaceous glands. The theory of Jonathan Hutchinson that leprosy may be contracted through eating diseased fish, or that the latter in some way may render the individuals susceptible to infection, has no foundation in fact. Hereditary acquisition of the disease is of doubtful occurrence, although the bacilli have been found in ova (Babès) and commonly are present in enormous numbers in the testicles. Hansen states, however, that he has never found them in the female generative organs.

Location of Bacilli.

The presence of large masses of bacilli in leprous tissues is a characteristic of the disease. To a large extent they are intracellular, and they are often grouped in such a way as to resemble bundles of cigars. Hansen believes that the bacillus is essentially an intracellular parasite, and that it becomes extracellular only as a result of degeneration and disintegration of infected cells. Unna, on the other hand, considers their location in lymph spaces as most characteristic. They appear to be carried to distant parts through the lymphatics. Certain large vacuolated cells, the lepra cells of Virchow, the *globi* of Hansen, which are filled to bursting with the leprosy bacilli, are characteristic of the disease. Unna and others consider these bodies as zoöglear masses rather than as intracellular accumulations, and Kanthack interprets them as bacillary thrombi in the lymphatic vessels. The nodules, or lepromas, consist of granulation tissue, containing many round and epithelioid cells, lepra cells and occasional multinuclear giant cells. In cutaneous macules columns of round cells surround the blood vessels, there is some proliferation of epithelioid cells and there are relatively few bacilli. The bacilli are most numerous in the nodular lesions, although they are present in large numbers in the secretions of the nose and mouth, as stated. They are found in the Glissonian tissue of the liver, in the pulp and follicles of the spleen, in the glomeruli and interstitial tissue of the kidney when these organs are involved, in the nerves in both the nodular and maculoanesthetic forms of the disease, and in the vascular endothelium. They have been demonstrated often in the ganglionic cells of the posterior root ganglia and of the spinal cord. Their occurrence in these cells leads Metchnikoff to say that the latter have phagocytic properties.

Endotoxin (?).

In view of the chronic course of leprosy and the absence of signs of intoxication over considerable periods, it seems probable that the bacillus secretes little or no soluble toxin. From time to time, however, patients with tubercular leprosy develop fever, which may persist for weeks or months and eventually terminate in death. During such attacks the nodules not infrequently enlarge, become soft and later disappear. Lie conceives that such periods represent massive infection of the blood with the bacilli, and that at this time the latter undergo extensive disintegration and liberate endocellular toxins to which the toxic phenomena are due. It is a remarkable fact that intercurrent infections, as measles and smallpox, and the administration of potassium iodid, cause a similar enlargement, softening and final disappearance of leprous nodules, accompanied by marked degenerative changes in the bacilli. Hansen is of the opinion that the fever induced by these conditions has an actual curative effect, although its influence is not readily analyzed. He quotes the opinion of Danielssen that potassium iodid may be used to determine the cure of leprosy, which would be indicated by absence of a febrile reaction.

General confidence is not felt in the "leprolin" which Rost prepared from his cultures of the leprosy bacillus (?). His cultures are said to have been mixtures of micro-organisms.

Susceptibility and Means of Defense.

Because of the failure to cultivate the leprosy bacillus, experimental work with the serum and cells of man and animals, by which conclusions as to the defensive powers of the body might be drawn, can not be carried out. It seems probable that all men are susceptible to leprous infection under the proper conditions. Sauton states that children of from 4 to 5 years are particularly liable to infection. Other conditions which may increase susceptibility are of a conjectural nature. It is possible that leprosy predisposes to tuberculous infection (?).

The condition in leprosy seems to be that of an organism of low virulence against which the body possesses no decisive protective agency. The reactions for the most part are of a local nature, involving the proliferation of connective tissue and blood vessels, and the accumulation of lymphocytes. That phagocytosis by macrophages (lymphocytes, connective tissue, endothelial and ganglionic cells) is a factor which antagonizes the proliferation of the bacilli is suggested by the large number of bacilli which are found in these cells.

Prophylaxis.

The principles of prophylaxis may be illustrated by citing the practices in Norway. Originally all lepers were confined to institutions. At the present time, however, only indigent lepers and those who can not be suitably cared for at home are required to enter an asylum, where they live under the best hygienic conditions. Other patients are allowed to remain at home, with the understanding that they sleep alone and, if possible, have separate rooms, that their clothing, linen and eating utensils be used by no one else, and that proper precautions be taken in the washing of linen. Dressings and bandages must be burned. Under these regulations the number of lepers in Norway has decreased from 2,870 in 1856 to 577 in 1900. Banishment to a particular island is practiced in the Sandwich Islands. Segregation of lepers should be brought about in this country.

Carasquilla attempted the production of an anti-leprosy serum by immunizing horses with the blood of leprous patients. Although a few favorable reports concerning its effects appeared it has not proved of value in the hands of others.

Truth and the Physician.—You need not tell all the truth unless to those who have a right to know it all. But let all you tell be the truth.—Horace Mann.

Clinical Reports

EPIDERMOID OF THE RIGHT SUBMAXILLARY REGION.

VICTOR SCHRAGER, M.D.
CHICAGO.

The present case is not reported because of its rarity, but simply because of its clinical importance.

Patient.—Physician, male, aged 60.

History.—In the spring of 1898 the patient noticed a small abrasion on the right side of the lower lip. Previous to that time he smoked cigars excessively. In December of the same year he ceased smoking, and by applying a saturated solution of acetanilid to the abrasion, it soon healed. Encouraged by the healing, he began to smoke again. A few months later, in 1899, there was a recurrence of the trouble. In August, 1900, he consulted a surgeon and immediate excision of the lesion was advised. Feeling some uncertainty as to the nature of his trouble, he had a microscopic examination made, and it was found that it was an "incipient epithelioma." In October, 1900, the epithelioma was cauterized with chromic acid. The ulcer healed, but it left some induration. In the fall of 1902 it recurred. In September, 1904, it was cauterized again with chromic acid and x-ray exposures were advised. After fourteen x-ray treatments the epithelioma healed very nicely and continued to remain healed.

Examination.—In February, 1905, the patient discovered an oblong swelling below the angle of the right inferior maxilla. He came to Dr. Murphy's office for examination, and an oblong swelling the size of an almond was found, situated as stated above. It was firm of consistency, very slightly movable and adherent to the subjacent tissues. Pressure and manipulation did not cause pain. The patient stated that since the appearance of the swelling he had lost some weight and strength. He also stated that the increase in size was very gradual and slow at first, but that during the last few weeks it had increased rapidly. Considering the patient had an epithelioma diagnosed by the microscope, his age, the relative wasting symptoms, the situation of the swelling in the lymphatic area on the corresponding side, and fixity of the swelling, it was concluded that there was epithelial metastasis in a lymph node. The patient being a physician was not surprised by the diagnosis. He firmly believed that he had a recurrence of carcinoma, and for this reason he was ready to give up his practice and to settle all his affairs in view of future unpleasant events. In spite of his age the man was unusually robust and had no other reason for discontinuing his practice.

Operation.—May 20, 1905, the patient was operated on. The mass had the appearance of a lymph node and was perfectly incapsulated; it was somewhat adherent to the surrounding tissues and was easily enucleated. The patient left the hospital a few days after the operation. The wound healed rather slowly and left an induration in the scar.

Microscopic Examination.—When this specimen was examined in the laboratory an elliptical mass encapsulated in a smooth, intact capsule was found, and a longitudinal incision revealed a whitish pulp containing a cyst cavity in its center. Sections were taken from the pulp and hardened. The microscopic examination of sections showed several undulated layers of epithelial cells, which reproduced perfectly the histologic structure of the skin. Below these layers two three hair follicles and vessels were found; the rest of the tissue was occupied by connective tissue and marked round-cell infiltration. No sebaceous glands were found. A diagnosis of infected epidermoid was made. Prof. Robert Zeit based the diagnosis of epidermoid on the absence of sebaceous glands. Had these glands been present the diagnosis would have been dermoid.

Remarks.—This case illustrates the following points:

1. One should not be too positive of diagnosis of epithelial metastasis when a swelling is discovered on the corresponding side of an epithelioma of the lip. Such a mistake may have serious social results, especially in the case of men engaged in active work and of neurotic temperament!

2. The wasting symptoms and the gradual increase in size,

which are classical elements in the diagnosis of malignant conditions, may be explained in this case by the mental worry of the patient, which is liable to reduce weight, and by the beginning of infection of the epidermoid.

3. Every specimen removed by surgeons should be carefully examined microscopically. At the time of the operation the nodule did not impress the surgeon as being malignant, yet a positive diagnosis could not be made at that time. It is of primary importance that a microscope should be resorted to and the final diagnosis based on the histo-pathologic findings only. Had not this specimen been examined microscopically the case would probably have been recorded as one of permanent cure of carcinoma.

In connection with enlargements or tumors occurring below the inferior maxilla it should be remembered that accessory thyroids may occasionally be found there.

In conclusion I wish to acknowledge my indebtedness to Dr. J. B. Murphy for permitting me to report this case.

UMBILICAL HERNIA PERFORATING THE ABDOMINAL WALL.*

MYRON METZENBAUM, B.S., M.D.
CLEVELAND, OHIO.

Patient.—Woman, an imbecile, aged 56, about 3 feet 2 inches in height; weight, 135 pounds.

History.—For more than twenty years it was known that she had an umbilical hernia. During the past four years the hernia was of such proportions as to indicate that it was formed of a very large portion of the small intestines, with a large part of the omentum. The hernia was never reducible; there always remained a considerable portion of the intestines out of the abdominal cavity. The hernial opening permitted only two coils of the bowel to slip by each other.

The woman aided in performing simple household duties, was able to take care of her person to a very fair degree, but under no condition was it possible to train her to wear an abdominal support.

On the evening of March 19, 1904, the people with whom she lived noticed that her outer skirt was wet and attempted to find the cause. They were resisted with such violence as to compel them to abandon the examination. Early on the following morning I was called, and, on entering the room, was almost overcome by the foul odor, suggesting gangrene.

Examination.—The patient was up and about. I induced her to go to bed, and, on removing her clothing, which was thoroughly saturated, the following unusual condition was observed:

The hernia was much larger than usual, causing the abdomen to protrude upward at least ten inches in height. In the region of the umbilicus the abdominal fat has been worn away, so that in this region the bowels were only covered by the skin. Here there was a circular area 2½ inches in diameter which had become necrotic. At the place where the umbilicus should have been there was a hole fully one inch in diameter, through which the umbilicus and what I thought to be the urachus dangled out on to the abdomen. No attempt was made to reduce the bowel, but a binder was fastened around the abdomen and the patient was removed at once to the Mt. Sinai Hospital for immediate operation.

Up to that time she had not vomited. Her pulse was about 86; temperature normal. She did not seem to be suffering the slightest pain and, judging by her features alone, one would not know that anything was ailing her. She had eaten some breakfast and wanted to engage in her usual duties. The servant was of the opinion that her bowels had moved on the previous day.

From these symptoms I did not consider that there was either strangulation or torsion of the bowel, but that a greater amount of the bowel than usual had been forced through the abdominal opening, causing a very great pressure on the thin abdominal skin and producing necrosis.

Operation.—Within an hour from the time I first saw the patient she was on the operating table. With the kind services of Dr. C. A. Hamann, the following operation was performed and the following conditions observed:

Nearly all the small intestines, together with the cecum and appendix and a large portion of the omentum, comprised the hernia. Loops of intestines were grown together with masses of the abdominal fat and omentum, and in many places were firmly adherent to the abdominal wall itself. It was for these reasons that the hernia was never reducible.

The opening in the abdominal wall was not over 1½ inches in diameter, so that the cecum, once being forced through, could not slip back into the abdominal cavity. That which I had considered the urachus dangling through the perforation was a Meckel's diverticulum. This was gangrenous and was amputated, as well as part of the omentum. The bowel itself seemed healthy. The fluid which saturated her clothing was peritoneal fluid and serum exudate from the bowel.

After long and tedious work, the various adhesions of the bowel were broken up, but only after unusual effort was it possible to replace the intestines in the abdominal cavity.

Postoperative History.—The abdominal opening was closed. The time required for the operation was one hour and forty minutes. The patient was returned to bed, and soon it became necessary to administer artificial respiration and frequently thereafter, for it seemed as though her respiratory center was interfered with in a very marked degree. She rallied from the operation, her bowels moved at the end of twenty-four hours, she took considerable nourishment, and became about as intelligent as ever. On the third day a double lobar pneumonia developed, and she died on the evening of the fourth as a direct result of the pneumonia. Up to this time the abdomen remained flat, with no unusual tenderness or soreness and no evidence of peritonitis.

GUNSHOT WOUND OF THE BOWELS.

O. S. HUTCHINS, M.D.
CANBY, MINN.

Patient.—June 18, 1905, a girl, 13 years of age, while carelessly handling a 22-caliber rifle, shot herself in the abdomen one and one-half inches to the right and slightly below the middle of a line drawn from the umbilicus to the os pubis. She resided at a farmhouse ten miles in the country. Patient had vomited before I reached her, four hours after the accident, and was in considerable pain with limbs drawn up. There was increased pain on slight pressure over the bowels. Considerable shock was present.

Operation.—Preparation for operation was commenced immediately. Under anesthetic, median incision was made into peritoneum. Considerable free and clotted blood was found, which was scooped out. The first loop of bowel in region of entrance of bullet into peritoneum was grasped, pulled out, and six openings in the small bowel were found in searching nearly its whole length. The openings were closed with Lembert sutures of linen (Pagenstecher). The cecum was then examined and a slit one and one-half inches long near the appendix was found penetrating all the coats of the bowel. A piece of feces which projected from the opening was removed with gauze sponge and this opening was closed as before. Drainage was introduced down to the points of suture in cecum and intestines; also into cul-de-sac of Douglas.

Convalescence.—Bowels moved on third day after repeated small doses of calomel followed by enema. Drainage was gradually removed after the third day. Temperature remained from 99 to 101 for three weeks, when swelling developed above the lower third of Poupart's ligament, and in a few days an abscess discharged through the opening left for drainage. After this there was an uninterrupted recovery. Patient was out of bed at the end of the sixth week with small fistulous opening at lower angle of wound, which had completely closed two weeks later. Bullet was not searched for.

NEW OBSERVATIONS ON HYDROPHOBIA.

There are many points of extreme interest in connection with hydrophobia. Thus, the affinity of the as yet unknown virus for the nervous tissue can not but excite our curiosity, but not to any higher degree than does the very highly specialized mode of elimination selected by this virus, namely, by way of the saliva. There has been some doubt expressed as to whether or not the saliva of human beings suffering from hydrophobia contains the virus. There seems to be no question, however, but that in many cases the saliva of hydrophobic patients is virulent. Recently Bertarelli[1] demonstrated such to be the case in an instance of hydrophobia in a boy. It is interesting to note that Bertarelli found the saliva in this case to be virulent after being filtered through a Berkefeld filter No. 5, thus confirming the observations by Remlinger and others that the virus of hydrophobia belongs in the group of filterable virus. So far, the filterability of virus through filters that ordinarily hold back the smallest known bacteria has been explained as due to the minuteness of the organisms or particles concerned, but other explanations have been suggested also.

Tizzoni and Bongiovanni[2] are studying the effects of radium on rabies, and report that the application of radium to the eye of rabbits injected with fixed virus prevents the development of rabies and may even cure animals in which active symptoms of rabies have become manifest. They found also that radium *in vitro* rapidly changes fixed virus to an excellent vaccine. In the rabid animals treated with radium the nervous disturbances subside first, followed by recession of the fever and the loss of weight. The results reported by these investigators exceed those so far attained by any of the other methods of treatment in vogue, which have little or no effect on the march of the fully developed disease.

On the basis of the results of their experiments, the Italian workers express themselves as willing and ready to apply the radium treatment to hydrophobia in human beings. Should their anticipations be realized fully, a great advance will have been achieved in the treatment of this dreaded disease, many victims of which now succumb because for various reasons the Pasteur treatment, which is successful only when applied early in the period of incubation, is delayed or neglected until too late. The results of the radium method of treatment in established hydrophobia will be awaited with the greatest interest.

IMPROVED CONDITIONS ON THE ISTHMUS OF PANAMA.

The epidemic of yellow fever in the southern states has diverted attention for a time from that and other diseases on the Isthmus of Panama and from the activities of the sanitary department of the Canal Zone Government. The report of Colonel Gorgas for July was very encouraging, for, with the exception of yellow fever, there were no quarantinable diseases, which include smallpox and plague, with both of which the isthmus is more or less constantly menaced. Of yellow fever there were but 42 cases in a total population of a little over 52,000, including the cities of Colon and Panama, and of these but 21 developed among the nearly 11,000 employes within the zone. There were but 5 deaths from yellow fever during July—just one-half the smallest, one-fifth the average and one-tenth the largest July yellow fever death rate under the French. The August report[1] shows that the yellow fever incidence had dropped to a total of 27 for the month, the lowest number since April. Since the date of this latest official report the yellow fever situation has continued to improve. Thus, a more recent press dispatch states that "Panama is at last free from the yellow fever. There is but one patient under treatment and he is well along toward convalescence. Hardly time enough has passed yet to be sure that there will be no recurrence, but strong hopes are entertained that the epidemic is a thing of the past. As for the bubonic plague, there has been no case since August 26, and the scare is fast dying out." In criticism of this correspondent it should be said that at no time since the American occupation has yellow fever been "epidemic." Perennially endemic before that time, it is to the credit of Colonel Gorgas and his splendid corps that the disease has been kept from endemic down to sporadic. It was never permitted to become epidemic in spite of the fact that thousands of non-immunes have been sent into the Canal Zone. President Shontz of the commission, on his recent return from the isthmus, reported to the Associated Press an improvement in all sanitary conditions on the isthmus and especially in the appearance of the men employed —a change which he attributed in large part to the improved quarters and to the better quality of food supplied under the present commissary arrangements.

But yellow fever is, by no means, nor has it ever been, the greatest scourge of the isthmus. An examination of the French records since 1882 reveals the fact that, in the city of Panama, the deaths from malaria have at all times been many-fold greater than those from yellow fever. Associate this with the fact that the mortality from malaria is over fifty per cent. less than that from yellow fever and it will be appreciated that the incidence of the former is very great. In the report of deaths from malarial fever, however, there is as much evidence of improvement as from the more dreaded yellow fever. Thus, during the first seven months of this year, there were but forty-one deaths from this cause. Contrast this with the French records, which showed 133, the lowest number of deaths from this cause, and 687, the highest, with 497, 481, 562 and 448 as examples of intervening figures, and the results of advanced sanitation become apparent. These results have been achieved by a comprehensive campaign, which has embraced the diminution of the anopheles through drainage, fumigation, the use of oil and the introduction of better water supply; the isolation of malarial patients in screened cages and screened wards; and the prophylactic use of quinin as a ration to the healthy.

[1] The Journal, October 7, p. 1095.

The better order of things that came after the reorganization of the commission by the President has been nowhere better exemplified than in the almost unhampered liberty that has been given to the sanitary department. This liberty, we understand, is practically restricted only by the money that may be available for sanitary purposes. If this is the case it is safe to assume that one of the most important and necessary items of expenditure will be for close-meshed wire netting with which to screen every barrack, bungalow, office, residence, shop or other structure to be occupied at night by any person, from the commonest laborer to the governor of the Zone. But just here it should be urged that, if the mean health rate is to be maintained at anything like the standard of effectiveness, military discipline must be enforced, by which practically the entire personnel will be compelled to protect themselves against the anopheles. These Colonel Gorgas has shown to be very generally infected and they are accordingly dangerous to all who may be exposed to their bites.

On the isthmus, as at New Orleans, the campaign against mosquitoes is one of primary importance, with the difference that on the isthmus there is never such a thing as a frost to help out the sanitary officers. Quite to the contrary, the weather and the topography of the country there combine to propagate the troublesome pests every day of the year. The report for August emphasizes the fact that the rainy season has set in and that the utmost vigilance and activity is required to keep breeding places for mosquitoes from forming. It has been found necessary to make the maintenance of such breeding places under certain circumstances a finable offense—an excellent stroke of policy that will insure at least partial co-operation of the populace. The real task remains, however, to be performed by the regular sanitary service and it is against tremendous odds that the mosquito brigades have to contend. Their work is, indeed, fraught with such importance that the report of their operations becomes extremely valuable, the element of novelty adding not a little to the interest. Thus we read that the great administration building has been made "stegomyia proof"; that in this great building all containers have been inspected daily and "no eggs of stegomyia or other mosquitoes were found during the month." We are told that "there is a noticeable decrease in the number of stegomyia present in Santa Ana Park since the same was trimmed out by this department in June"; that "all houses and yards are inspected at least every six days"; that "every room of each house is carefully inspected for mosquito larvæ in water containers placed therein," and that "mosquito larvæ (mostly in the early stages of development) were found in 579 of the houses inspected." Brigades of oilers are at work; drainage brigades are after the anopheles; and still other brigades are fumigating the houses. A dozen tons of sulphur and nearly as much pyrethrum have been used in a single month. Pools, tanks, barrels, and sluggish streams are covered with oil. Thousands of crabs have been killed and more thousands of crab holes—propagating places for mosquitoes—have been closed. Cesspools and drains have been cleaned; garbage and vegetation removed. Then, too, the threatened invasion of the isthmus by the bubonic plague has started up the rat-killing business and brigades are out after the rodents, while free rat traps are being distributed to the populace. When, finally, we add to this the treatment of the sick, the ever-vigilant quarantine service, the sanitary construction work and the thousand and one incidental things that must be done in an administrative way, then the picture becomes a little more complete.

We can not refrain from a suggestion to the bureau of vital statistics of the Zone government, and that is to give the adult population and the adult deaths in such wise that the death rate may be designated on an adult basis. This is the point of practical interest in the states where everybody, but especially prospective employes on the isthmus, are concerned about the liability to disease and death incurred by adults who go to the Zone. The summarization, for example, in the last report by simply giving the total number of deaths 265, to a total population of nearly 54,000, is misleading, or at least confusing, and gives the isthmus a less satisfactory reputation than it is entitled to. The impression prevails that these deaths are chiefly among adults, whereas an analysis of the table of "deaths by ages" reveals the fact that 101—nearly two-fifths of the entire number—occurred under 20 years of age. Considering the fact that adults are probably much in excess of sixty per cent. of the entire population, it follows that the death rate among adults must be less than that indicated as the annual average, either for employes of the commission, 35.93 per 1,000, or for the general population of Colon, Panama and the Zone, 64.95 per 1,000.

IS TYPHOID CONTAGIOUS?

A correspondent calls our attention to an editorial in the Grand Rapids *Herald* with the above caption and to the important difference between its teaching and that of former days in regard to the contagiousness of typhoid fever. According to this editorial, Dr. Vaughan of Ann Arbor and others have advanced the idea that typhoid fever is communicated largely by personal contact. Dr. Vaughan is quoted as having made this statement: "I formerly held the view that 95 per cent. of the typhoid fever was transmitted by drinking water . . . but the experiences and information collected by the commission (appointed by the Secretary of War to study the origin and spread of typhoid in the military camps during the Spanish-American war) led me radically to change my views. I believe now that the spread was largely by personal contact. From the observations made, I reached the conclusion that under the conditions maintaining in military camps, personal contact was responsible for the spread of the disease in about 66 per cent. of the cases."

The view here announced is in harmony with recent knowledge in regard to the elimination and spread of the typhoid bacillus and the communicability of typhoid fever. The commission just mentioned rendered a most valuable service in calling attention to the ease with which typhoid fever may be disseminated by other means than infection of water, which, nevertheless, remains the most common origin of sudden, ordinary epidemic outbreaks of the disease. The report[1] of this commission has been published and should be studied carefully by all that are interested in preventing typhoid fever.

Now, the contagiousness of typhoid fever is not to be so understood that the mere presence only of a susceptible person in the vicinity of a typhoid fever patient is dangerous. We know that typhoid bacilli are eliminated from typhoid patients by way of the feces in all cases, by the urine in a large percentage of the cases (at least 25 per cent.), and occasionally by the sputum. Contamination of the surface of the patient himself and of his immediate surroundings, consequently, is practically unavoidable. When little care is used there is the greatest opportunity for wide dissemination of the bacilli by contact. We know that flies may convey the bacilli and deposit them on various substances, including food and drink, in which the germs may multiply. "Fingers, food and flies are the chief means of local propagation. It is impossible for a nurse to avoid finger contamination" (Osler). All hospitals have "house" infections of typhoid fever in physicians, nurses, orderlies, laundry employes, etc., in spite of special precautions, and not a few deaths among house officers have resulted from typhoid so contracted.

It is unquestionably becoming recognized more and more that contact infection is an important means of spreading typhoid fever wherever it breaks out. Thus, Newman, in London, lays great stress on direct infection, the importance of which is emphasized also by F. Klemperer in Berlin. In country communities the spread of the disease when once introduced is often explainable in no other way because here we can not always fall back on a common water or milk supply, and country physicians would do well in publishing observations in point.

In view of the comparative ease with which contact infection may take place, it is rather strange that the doctrine denying case to case contagion should have survived so long. Undoubtedly, this is due to the fact that all the possibilities of direct and indirect contact infection could be fully recognized only as the bacteriology of the disease became fully understood, and much of our knowledge concerning the elimination of typhoid bacilli, their viability outside the body, their conveyance by flies, etc., is recent.

The practitioner should base his prevention of typhoid fever on the fact that it is caused by the typhoid bacillus and that this is eliminated in virulent condition from all typhoid patients in such manner and number as easily to cause infection by contact as well as through water supply. On this account, it is clear that cases of typhoid fever, in the hospital as well as in the home, should be segregated carefully until such time as neither feces nor urine contain bacilli.

THE LESSON OF THE EPIDEMIC.

The hopeful prediction of The Journal has been fulfilled. The yellow fever epidemic is so nearly at an end that it can safely be said that science has won a distinct victory after one of its greatest battles. The attitude and the effort of the community have been admirable and thoroughly helpful to the enlightened and vigorous course of the officers of the United States Public Health and Marine-Hospital Service. Action along the lines pointed out by the mosquito theory of infection has proved to be absolutely effective. This is demonstrated by comparisons with the epidemic of 1878. The two epidemics were discovered late in July and they ran a very similar course up to three or four days after the beginning of the organized fight this year. Thereafter the cases decreased in 1905 as against a great increase in 1878. In all the South there have been in 1905 less than 9,000 cases and not over 1,000 deaths, while in 1878 in New Orleans alone, with half its present population, there were 4,000 deaths. In 1905 outside New Orleans it has been shown, in town after town, that the epidemic recedes uniformly when there is thorough application of the methods deduced from the mosquito doctrine. Whenever the community has been reluctant to adopt the measures demanded by modern knowledge, there the epidemic has been most severe. If the South will see the lesson and insist on its application, there surely will never be another epidemic of yellow fever in the United States. The medical profession of the southern states faces a great responsibility. In every locality it must teach the lesson of the epidemic and be insistent on the adoption of those precautionary measures that have been proved to be effective and to be absolutely indispensable.

[1] Report on The Origin and Spread of Typhoid Fever in U. S. Military Camps During the Spanish War of 1898.

NEWSPAPERS THAT DECEIVE.

The newspapers of the country, as a class, are sufficiently true to the responsibilities of their position in directing the thoughts of the people to make the flagrant exceptions which are frequently noticed to stand out in most unwholesome prominence. Two medical pretenders in Des Moines were allowed to purchase space in the Des Moines newspapers and nothing was published about them except in their approval. The editor of the *Iowa Medical Journal*[1] inquired of a reporter why the arrest of these men on the charge of fraud was not mentioned, and was told that it had been "overlooked." He went to the city editor of the largest daily paper in Des Moines with some facts concerning the case; he was cordially received and was assured that the facts would be published, and that the news columns were not influenced in any way by the advertising department. The next morning not one word appeared in the paper concerning the arrest and trial. On the contrary, there appeared a column article, presumably written by the offenders, and derogatory to the profession of Des Moines. Later, when the courts decided against the fraudulent practitioners, thus putting an end to the possibility of a money income for advertising, the daily press had plenty to say about the "victory achieved in interest of good government," etc. This is one of the glaring offenses against honesty which tend to make the careful reader doubt almost every statement in such a paper. But the newspaper which allows the character of its contents to be influenced by pecuniary considerations is not alone to blame. The public which continues to read such a paper must bear a part of the responsibility.

TREASON AGAINST THE GOVERNMENT.

The New Orleans *American* (sadly misused name) of Oct. 5, 1905, in an editorial, accused the United States Public Health and Marine-Hospital Service of failing to combat successfully the epidemic of yellow fever and of boodling. At this late date it even sneeringly questioned the existence at any time this year of yellow fever in New Orleans. Among other things, it said: "The campaign of the Marine-Hospital Service against the so-called yellow fever is an absolute failure." This "means loss for the many, profits for the few." Then it demands the "expulsion of the boodlers." It is one thing to discuss debatable theories and to expose dishonesty wherever found, but the events of the epidemic can not by any artifice be twisted into any excuse for this offense of the New Orleans paper. To the credit of the press it may be said that few papers have ever approached this depth, for this denotes hopeless depravity. The time is close at hand for the creation by statute of a new variety of treason. If it is treason in time of war for a man to betray his country's military plans, it certainly should be made treason for a man or a publication in time of deadly peril from disease to foment by false allegations public lack of confidence in the government's plan of rescue, and in the integrity and ability of the men who risk their lives to save the community from unnecessary deaths. Than this no treachery can be more base. Physicians, citizens and the reputable press should join in asking stringent penalties for this crime against the nation, against humanity.

ADDITIONAL ALCOHOLIC COMPOUNDS TO BE TAXED.

We commented recently on the Internal Revenue ruling by which compounds which are composed chiefly of distilled spirits are to be classified as alcoholic liquors unless it can be shown by the manufacturer that substances undoubtedly medicinal in their character are used in sufficient quantity to give a medicinal quality to the liquor other than that inherent in the alcohol. A subsequent ruling[1] includes malt extracts in the alcoholic compounds so to be taxed. Further, essences or extracts, such as of lemon, vanilla, etc.—which, being household articles for culinary use—would ordinarily not be included in the ruling, will come under the ruling whenever they are found by the local internal revenue officers to be generally used and sold as beverages, especially in prohibition districts. Thus it is seen that the interpretation of this ruling is broad and yet specific, while at all times fair. Whenever a composition is really used as an intoxicating liquor, it must meet the requirements of law laid down for the sale of liquor.

RIGHTS OF PURCHASERS.

Since every one is a purchaser, directly or indirectly, it is a problem of universal interest as to how one may be sure that the goods purchased at any time or place were prepared for the market so as to be free from disease. In an interesting article[2] on this subject, Mrs. Florence Kelley, secretary of the National Consumers' League, gives an insight into the problem. Goods supposed to have been made in a department store's "own factory" have been found to come from squalid, filthy sweat-shops. It was found to be impossible to depend on the statement of many stores concerning the origin of goods. A woman in the last stages of consumption was found making little boxes for wedding cake, moistening gummed edges with her tongue. A man with tuberculosis, and whose son had an external cancer, earned money by cracking walnuts. A $60 overcoat, supposed to have been made to order by a merchant tailor in Helena, Mont., was really made in an eastern city in a tailor-shop where a case of smallpox existed. Mrs. Kelley remarks: "It would seem an obvious right of the purchaser that the food which he buys at the price asked should be pure and clean; that the garment purchased of an entirely reputable dealer should be free from poisonous dyes, vermin and the germs of disease; and that both food and garments should leave his conscience free from participation in the employment of young children or of sweaters' victims. Yet these seemingly obvious rights were perhaps never farther from attainment than to-day, in the opening years of the twentieth century. Adulteration of foods has never in the history of the human race been carried on on a scale so vast as at present. The sweating-system, with its inevitable accompaniment of filth and disease conveyed in the product, persists and increases in spite of sixty years of effort of the philanthropists and the needle-workers to check it." A few individual inspections of such cases as are referred to in the article will do more to convince one of the way in which the rights of purchasers are ignored than volumes of argument.

Medical News

COLORADO.

Staff for Moffat Road.—Dr. Lewis F. Lemen, assisted by Dr. Hugh L. Taylor, has begun the work of organizing the medical and surgical department of the Moffat system.

Denver to Have Emergency Hospital.—Denver is to build an emergency hospital in a central location, at a cost of $40,000. The new institution will be under the supervision of the city board of health, the commissioner of health being directly in charge.

New Editor.—Dr. J. M. Blaine has resigned as secretary of the Colorado State Medical Society to become editor of *Colorado Medicine*, the official journal of the state society. Dr. Melville Black of Denver succeeds Dr. Blaine as secretary. Dr. Edward Jackson, formerly editor of *Colorado Medicine*, retires from the editorial position, but remains on the publication committee.

CONNECTICUT.

Money for Hospitals.—By the will of Elbert A. Woodward $5,000 is bequeathed to Norwalk Hospital for the endowment of a free bed to be known as the Woodward Fund bed.——The fête recently held for St. Vincent's Hospital, Bridgeport, netted $1,047.52 to the institution.

Infectious Diseases.—During September 27 cases of measles were reported in 10 towns; 88 cases of scarlet fever in 32 towns; 5 cases of cerebrospinal fever in 3 towns; 92 cases ot diphtheria in 26 towns; 25 cases of whooping cough in 10 towns; 316 cases of typhoid fever in 58 towns, and 36 cases of consumption in 11 towns.

Personal.—Dr. Charles B. Graves has been elected president and Dr. Abiel W. Nelson a member of the executive committee of the Mainwaring Memorial Hospital, New London.——At the annual meeting of the Litchfield County Hospital Dr. William S. Hulbert, Winsted, was elected a director.——Dr. Charles H. Glover, Norwalk, has been appointed a member of the medical staff of the Connecticut Hospital for the Insane, Middletown.

September Deaths.—During the month of September only 1,195 deaths were reported, 222 less than in the previous month, 26 more than in September of 1904, and 5 less than the average for September during the five preceding years. The mortality was equivalent to an annual rate of 14.5 per 1,000. Infectious diseases were responsible for 196 deaths, or 16.4 per cent. of the total mortality. The chief death causes were: Diarrhea, 150; diseases of the nervous system, 138; consumption, 111; heart disease, 109; accidents and violence, 90; pneumonia and typhoid fever, each 35.

DISTRICT OF COLUMBIA.

Board of Charities Estimate.—The secretary of the Board of Charities has submitted his annual estimate for the next fiscal year to the commissioners of the district. The schedule is less by about $200,000 than that sent in by the Board of Charities last year.

Personal.—Dr. Henry D. Fry is entertaining his guest, Prof. Carl von Noorden of Frankfurt-a-Main, at his residence. A card reception was held October 21 in his honor.—Dr. W. Robert Perkins, formerly resident physician at the Central Dispensary and Emergency Hospital, has returned to the city and taken up his practice.

Health of the District.—The report of the health officer for the week ended October 14 shows the total number of deaths to have been 95, of which number 61 were white and 34 were colored, and 21 stillbirths, of which number 6 were white and 15 colored. The total number of births was 164; whites, 116; colored, 48. There were 27 cases of diphtheria, 10 of scarlet fever, 228 of typhoid fever and 1 of smallpox under treatment at the close of the week.

ILLINOIS.

Hospital Incorporated.—The Graham Hospital Association and Training School for Nurses has been incorporated at Canton by C. F. Everly, M. Addie Dewey and Oscar H. Parks.

Physician Wins Suit.—In the damage suit of Paul F. Kline against Dr. Edgar H. Little, East St. Louis, in which $5,000 was claimed for alleged malpractice in the setting of a broken arm, a verdict was returned October 17 in favor of the defendant.

Diphtheria Closes School.—One of the schools of Ottawa has been closed on acount of the existence of 10 cases of diphtheria among its pupils.——The grade school at Desplaines has been closed on account of diphtheria; 3 cases have been reported, with 1 death.

Personal.—Dr. Arthur F. Comings, Rockford, has retired from the medical profession and will go into business in Sterling.——Dr. Joseph Scheurich, Philo, who was recently shot, is convalescent and has returned to his home.——Dr. Fremont C. Knight, Waukegan, has been appointed chief surgeon of the Chicago & Milwaukee Electric Railroad.

Staff Examination.—More than 300 physicians have signified their intention to the county civil service commission to take the examination for places on the Cook County Hospital staff. The examination opened October 23 and will close November 27. All examinations are being held at the County Hospital. The dates of examinations in the various subjects are as follows:

Oct. 23, Skin diseases; Oct. 26, X-Ray and diseases of the eye. October 30, Diseases of the ear, nose and throat; November 2, Obstetrics; November 6, Diseases of children. November 9, Contagious diseases; November 13, Pathology; Nov; 16, Nervous and mental diseases; November 16, Pathological chemistry; November 20, Medicine (general); November 24, Orthopedic surgery; November 27, Surgery (general).

Chicago.

Hospital Incorporated.—The Ravenswood Hospital has been incorporated with a capital stock of $50,000 to maintain a hospital and training school for nurses by Drs. George W. Green, George M. Bussey and Ernest A. Fetherston.

Personal.—Dr. P. J. H. Farrell has been elected surgeon-general of the Army of the Philippines.——Dr. John E. Owens has been re-elected a trustee of St. Luke's Hospital.——Dr. Carl L. Barnes has gone to California.——Dr. John B. Murphy was given the degree of Doctor of Science at the convocation of the University of Illinois, Champaign, October 2.

Deaths of the Week.—The total deaths from all causes of the week ended October 21 were 466, 11 less than for the previous week and 4 more than for the corresponding week of 1904. The annual death rate per 1,000 was 12.19. Acute intestinal diseases lead in the death causes with 64, followed by consumption with 55; violence, including suicide, with 46; Bright's disease with 45; pneumonia with 44; heart diseases with 32, and cancer with 22.

Gynecological Society Election.—At the annual meeting and dinner of the Chicago Gynecological Society October 20 the guests of honor were Drs. Hunter Robb, Cleveland; Frank Billings and Henry S. Tucker, Chicago, and Matthew D. Mann, Buffalo, N. Y. The following officers were elected: President, Dr. Frank T. Andrews; vice-presidents, Drs. Joseph B. De Lee and Charles E. Paddock; secretary, Dr. Henry F. Lewis; treasurer, Dr. Charles B. Reed; pathologist, Dr. Gustav Kolischer; editor, Dr. Rudolph W. Holmes, and councilor, Dr. Franklin H. Martin.

Evils to be Avoided.—In an address on pneumonia delivered October 19 by Dr. Heman Spalding, he gave the following summary of evils to be avoided and precautions to be taken to keep the vital resistance of the body up to the normal standard:

Drunkenness; foremost among all the habits of mankind that ai[illegible] of the disease. Congested mucous membr[illegible]or the germ.

[illegible] digestion, interferes with circulation.

Failure to keep mouth and teeth clean; convenient lodging places for the ever present germ are afforded.

Overheated houses make persons too susceptible to outdoor cold; light clothing, including underwear, should be worn indoors.

Breathing through the mouth; bad for many reasons. Frequent baths will keep the skin active and free from effete material.

The Senn Banquet.—A banquet in honor of Dr. Nicholas Senn, professor of surgery, University of Chicago, and surgeon-general of Illinois, will be held at the Auditorium Hotel, November 11, at 6:30 p. m. No personal invitations will be issued, but every one is invited. Tickets for the banquet may be procured from Dr. D. J. Doherty, 100 State Street, Chicago. The price per plate is five dollars. Among the speakers will be Hon. George R. Peck, Dr. W. J. Mayo, Rochester, Minn.; Dr. Charles A. L. Reed, Cincinnati; Dr. Frank Billings, Chicago; Dr. Jacob Lang, Milwaukee, and Dr. John A. Witherspoon, Nashville, Tenn.

IOWA.

Sisters Accept Hospital.—The Sisters of Charity of the Roman Catholic Church have accepted the gift of Mercy Hospital, Webster City, erected at a cost of $35,000 by the late Jacob M. Funk.

Faith Doctor in Jail.—A fine of $300 was imposed on Louis Valeske, New Hampton, who pleaded guilty to an indictment charging him with practicing medicine without a certificate. In default of payment he was committed to the county jail.

Diphtheria Closes Schools.—Grant school, Des Moines, was closed October 10 on account of the prevalence of diphtheria among its pupils.——On October 13 the public schools of Corydon, with the exception of the high school, were closed on account of diphtheria.——The school at Wyaconda has been closed on account of an epidemic of diphtheria.——Moreland reports 30 cases of diphtheria and 1 death.

"Great Paul" Pleads Guilty, Is Fined and Leaves State.—The patent medicine fakir known as "Great Paul," and who was arrested at Fort Madison, charged with practicing medicine without a certificate and who was later indicted by the grand jury, pleaded guilty in the district court, was fined $300 and costs, which he paid and immediately left town. Dr. C. F. Wahrer, the health officer of Fort Madison, took a leading part in ridding the city of this impostor.

Ill and Injured.—Dr. Wilton W. McCarthy, Des Moines, escaped with a bruised right hand from an accident which threatened to be serious. He was running alongside a moving train when he was struck by a car and knocked down, falling almost under the train.——Dr. D. H. Killingsworth, Clarinda, is critically ill.——Dr. Jason Roberts, Osceola, is seriously ill.——Dr. Albert P. Johnson, Sigourney, has so far recovered from his injuries that he is able to attend to business.

Personal.—Dr. John Elliott has resigned as city physician at Mount Pleasant and Dr. Walter A. Sternberg has been elected his successor.——Dr. Henry B. Jennings, Council Bluffs, has returned from abroad.——Dr. and Mrs. William B. La Force, Ottumwa, have returned from Holland.——Dr. John N. Warren, Sioux City, has returned from Europe.——Dr. John F. Ritter, Maquoketa, has returned from a four months' vacation in Virginia.——Dr. and Mrs. Frank B. Whitmore, West Union, sailed for China, October 10.——Dr. Timothy J. Caldwell, Adel, has gone to Fort Bragg, Cal., for the winter.——Dr. William E. Owen and family have returned from a trip to the Pacific Coast.——Dr. Edward M. Arenschield, formerly of South Ottumwa, has located in Glendora, Cal.——Dr. Charles M. Mackin, Independence, has been appointed assistant superintendent of the Clarinda State Hospital.

MARYLAND.

Old Letters.—The University of Maryland monthly, *Old Maryland*, is publishing interesting extracts from the letters of a Baltimore medical student in London during the years 1786 to 1789.—— *Old Maryland* has been made the organ of the University of Maryland Alumni Association.

Society Election.—The University of Maryland Medical Society has elected the following officers for the year: President, Dr. Harry Adler; vice-president, Dr. Fairfax Wright; secretary, Dr. Walter H. Mayhew, and executive committee, Drs. José L. Hirsh, R. L. Mitchell and Charles W. McElfresh.

Baltimore.

Election of Officers.—At the Johns Hopkins Hospital Medical Society Dr. William G. MacCallum was elected president, and Dr. Charles H. Bunting secretary.

Visitors from the Far East.—Dr. Ho Kan Yuen, fleet surgeon Imperial Chinese Navy, Hai Chow; Dr. Tsui Ying Young, surgeon-major Imperial Chinese Army, and Dr. W. P. Chung of the Government Hospital of Chinanfu, spent October 14 in Baltimore.

Will Continue Service.—The supervisors of city charities have decided to continue for 1906 the hospital and dispensary service as maintained in 1905. There are numerous applications from the hospitals and dispensaries all over the city, but besides having worked satisfactorily, the concentration of patients in a few hospitals allows a better oversight and inspection of patients and institutions.

Personal.—Dr. James G. Iglehart has been re-elected president of the Sons of the American Revolution in Maryland.——The vacancy caused by the death of Prof. Charles Schmidt, at the University of Maryland, will be filled temporarily by Prof. Charles Caspari, Jr.——Dr. Hugh Warren Brent has settled for practice in Baltimore.——Dr. William T. Watson has recovered from an operation for appendicitis.——Dr. Archibald W. Graham has been appointed assistant resident physician of Bayview Hospital, vice Dr. William W. Riha, made assistant physician at Danvers Insane Hospital, Hawthorne, Mass.

MASSACHUSETTS.

Home Dedicated.—The new convalescent home of the Children's Hospital, Boston, which is located in Wellesley, was dedicated by Rt.-Rev. William Lawrence, D.D., October 24, and opened for use.

Adulterators Punished.—Twelve milk dealers in Boston and one vinegar manufacturer were recently fined $10 each for adulterating. The vinegar man only a few weeks ago lectured in his native town on "The Dangers of Adulterated Foods."

Harvard Opening.—Harvard Medical School starts off with 13 graduate, 68 fourth-year, 65 third-year, 59 second-year and 76 first-year, students. This is a decrease of 8 from last year, but an increase in the first-year class of 10. Each of the other classes is smaller than it was last year.

Personal.—Dr. Anthyme S. Menard, the most prominent French physician in Holyoke, was seriously injured October 19 by a horse which became frightened at his automobile and fell into it, crushing him against the steering wheel.——Dr. Atwood R. Wood, Worcester, Mass., has been appointed superintendent of the Michigan Asylum for the Insane, Kalamazoo.

Hospital Concerts.—The November concerts of the Hospital Music Fund announced by Dr. John Dixwell are: November 4, Boston Insane Hospital; November 5, Somerville Hospital; November 8, Soldiers' Home; November 12, United States Naval Hospital; November 19, United States Marine Hospital; November 26, Boston Home for Incurables, and November 30, Massachusetts General Hospital.

Boston Medical Library Program.—The Boston Medical Library meetings are to be resumed October 28. As last winter, they are to be held in conjunction with the Suffolk District Branch of the Massachusetts Medical Society, at the Medical Library, on the Fenway, at 8:15 p. m. Light refreshments will be served at the end of each meeting. Twelve meetings are planned. The following is a preliminary program:

October 28: Semi-annual meeting of the Suffolk District Branch of Massachusetts Medical Society. The Committee on Tuberculosis will make a report on progress through Dr. Henry Jackson. "The Treatment of Surgical Tuberculosis in Children," by Dr. Edward H. Bradford, "The Duty of the City Toward Tuberculosis," by Prof. William T. Councilman. "The Home Sanitarium Treatment of Tuberculosis," by Dr. Joseph H. Pratt.

November 15: Moving pictures showing gaits, spasms and convulsions, Dr. Walter B. Chase, Brookline. Demonstrations with the Reflectoscope.

December 6: Surgical meeting. Subject of meeting will be announced later.

December 20: The milk supply of large cities. The program for this meeting has been arranged by Dr. Charles Harrington, secretary of the Massachusetts State Board of Health, who has invited speakers from other cities.

January 3: "Recent Advances in Physiology Bearing on Clinical Medicine," Prof. William T. Porter, Prof. Walter B. Cannon, Prof. Howell of Johns Hopkins.

January 24: "Surgery of the Peripheral Nerves," Dr. John B. Murphy, Chicago.

February 14: "The Military Hygiene of the Japanese Army," Captain Charles Lynch, United States Army.

February 28: "Secret Nostrums," Dr. Frank Billings, Chicago.

March 14: Surgical meeting. Subject to be selected by Dr. Joseph A. Blake, New York.

March 28: "The Treatment of Heart Disease." *a*, "The Use of Depletion," Dr. Frederick C. Shattuck; *b*, "The Use and Abuse of Digitalis," Dr. Franz Pfaff; *c*, "Pneumatic Differentiation," Dr. Charles E. Quimby, New York; *d*, "The Nauheim Treatment," Dr. Francis B. Kinnicutt, New York.

April 11: "Pyloroplasty and Gastroenterostomy," by Dr. J. N. T. Finney, Baltimore.

April 28: Semi-Annual Meeting of the Suffolk District Branch of Massachusetts Medical Society. Paper by Dr. Guy G. Fernald, Waverly, of the Maassachusetts School for Feeble-Minded.

NEW JERSEY.

Physician Left Fortune.—Dr. Frank L. Horning, Camden, has fallen heir to about $50,000 by the death of an uncle in Schuylkill County.

Appropriation for School Inspection.—The city council of Montclair has made an appropriation of $1,000 for medical inspection of schools.

Accidents.—Dr. William H. Pratt, Camden, narrowly escaped serious injury when his carriage was struck by a train October 11.——Dr. Alexander McAlister, Camden, was thrown from his carriage October 14 and seriously injured.

Hospital Elects Officers.—At a meeting of the board of directors of the Essex Private Hospital, Newark, Dr. John Dennis was elected president; Dr. Herbert W. Long, secretary; Dr. Theodore Teimer, treasurer; Dr. William O. Bailey, chairman of the executive committee, and Dr. William Buermann, chairman of the finance committee.

Hospital Staff Selected.—The board of governors of the Atlantic City Hospital has elected the following medical staff to serve one year from November 1: Drs. W. Blair Stewart, Elisha C. Chew, Theodore Senseman, Emery Marville, Edgar Darnell, A. Burton Shimer, Walt P. Conaway, J. Addison Joy, William M. Pollard, William H. Bennett and Joseph C. Marshall. Dr. Charles K. Mills, Philadelphia, was appointed consulting physician and Dr. W. F. Ridgeway pathologist of the hospital.

Personal.—Dr. and Mrs. C. D. Martinetti, Orange, sailed for Europe October 21 on the *Fuerst Bismarck*.——Dr. Katherine Porter, Orange, has returned from abroad.——Dr. Sidney C. Keller, Paterson, has been appointed a member of the resident staff of St. Elizabeth's Hospital, Utica, N. Y.——Drs. William A. Clark and Nelson B. Oliphant, Trenton, have returned from abroad.——Dr. Arthur H. Dundon, Plainfield, has been appointed registrar of vital statistics.——Dr. Immanuel Pyle, Jersey City, has been appointed successor to Dr. Stephen V. W. Stout on the staff of the City Hospital.——Dr. Dennis R. McElhinney, Elizabeth, has been appointed city physician vice Dr. George W. McCallion, deceased.——Dr. A. Haines Lippincott, Camden, has returned from a trip to Yellowstone Park and the Pacific Coast.——Dr. and Mrs. George W. Shera, Jersey City, have returned from a tour of the Great Lakes.——Dr. Talbot R. Chambers and family, Jersey City, have returned from Europe.

NEW YORK.

Hospital Opened.—The new Corning Hospital was opened to the public in connection with a donation party October 7.

Diphtheria at Oxford.—On account of the spread of diphtheria the Oxford schools were ordered closed October 11 for at least two weeks.

Medical Society Centennial.—The Washington County Medical Society celebrated its centennial at Sandy Hill October 3, 25 members being present.

Isolation Pavilion a Reality.—The woman's board of St. James' Mercy Hospital, Cornellsville, has raised a fund of $2,600 for the erection of an isolation pavilion, or $100 more than is required for the purpose.

Clerk of Health Department Removed.—Thomas Stuart, who has been chief clerk of the State Health Department for thirteen years, has been removed from office by the state health commissioner. It is claimed that this change was demanded for political reasons.

District Attorney Praised.—Drs. Henry R. Hopkins, Ernest Wende and Herman Hayd, Buffalo, give unstinted praise to Mr. Frank A. Abbott, first assistant district attorney, for his ability and the tenacity of his efforts to rid Erie County of the medical quacks and charlatans with which it has been infested for twenty years.

Cornerstone Laid.—The cornerstone of the new building for the Providence Retreat, Buffalo, was laid with appropriate ceremonies by Bishop Coulton, October 7. The institution is expected to be one of the finest in the United States for the care of the insane, will accommodate 186 patients and will cost about $300,000.

Hospital Loses Bequest.—In the suit of Edward Rosenbaum against Andrew Turnbull, executor under the will of Mary Rosenbaum, to break the latter's will, the Supreme Court decided in favor of the plaintiff. By this decision the German Hospital, Buffalo, loses the estate valued at $40,000, which was willed to it by Mrs. Rosenbaum.

Convalescent Home Opened.—St. Elizabeth Home for Convalescents at Spring Valley, Rockland County, was opened with impressive ceremonies by the Rt.-Rev. T. F. Cusack, auxiliary bishop of New York, September 14. The institution will accommodate 35 patients and will be open to persons of all denominations.

Library Association Election.—The Utica Library Medical Association held its annual meeting October 2, at which the following officers were elected: President, Dr. Thomas H. Farrel, Utica; vice-president, Dr. B. Pemberton Allen, Oriskany; secretary, Dr. Fred W. Smith, Utica; treasurer, Dr. James H. Glass, Utica, and librarian, Dr. Smith Baker, Utica.

Colleges Opened.—The Albany Medical College opened for its seventy-fourth session October 19, Dr. Albert Vander Veer delivering the introductory address. Dr. Holmes C. Jackson has been placed in charge of the physiologic laboratory and Dr. G. E. Bielby will assist in the department of histology. Dr. E. V. Fredericks has been made assistant in clinical microscopy, and Dr. C. Lannahan assistant in dermatology.——The sixtieth annual session of the medical department of the University of Buffalo opened September 25 with an address by Dr. George F. Cott.

New York Brought to Terms.—The strained relations which existed between the medical authorities of New York and New Jersey, which culminated in the recent action of the New Jersey authorities compelling New York physicians to submit to a New Jersey examination before practicing in that state and which was in retaliation for a similar restriction previously imposed by New York, have come to an end. At a conference of the representatives of the medical societies of the two states it was agreed that after Jan. 1, 1906, the authorities of each state should recognize medical certificates issued by the other state.

Personal.—Dr. Lucius B. Parmlee, Batavia, is spending the winter in Pasadena, Cal.——Dr. Mary O'Malley, Binghamton, has been appointed a member of the medical staff of the Government Hospital for the Insane, Washington, D. C.——Dr. Charles W. Chapin, Georgetown, has been appointed junior physician at the Manhattan State Hospital.——Drs. Harold G. Levy, Samuel H. Rosenthal, Arthur M. Johnson, Michael Casey and Edwin V. Rose have been appointed city physicians at Rochester.——Dr. William E. Silcocks, Green Island, who has been under treatment for appendicitis at Troy Hospital, has returned home.——Dr. Horace P. Pritchard, Cicero, has been made house surgeon at St. Joseph's Hospital, Syracuse; Dr. Maxwell Montgomery, house physician; Dr. Frank E. Eustin, assistant house surgeon, and Dr. Otto Weiscotten, ambulance surgeon.——Dr. Charles H. Langdon, assistant superintendent of the Hudson River Hospital, Poughkeepsie, was operated on for appendicitis October 3.

New York City.

Insane Transferred.—Fifty female insane patients were transferred from the Manhattan State Hospital to the Binghamton State Hospital October 11.

Hospital Sold.—The lot of ground on which is situated the old Harlem Hospital and the pier used by the city for its ferry to Randall's Island has been sold.

College Opens.—The sixty-fifth year of the New York University Medical Department opened October 4. The opening addresses were made by the dean, Egbert Le Fevre, and Chancellor McCracken.

Another Ambulance Accident.—An ambulance from St. John's Hospital, Brooklyn, was struck by a Marcy Avenue car at Bergen Street and Classon Avenue. This is the tenth ambulance accident in Brooklyn since Memorial Day.

Gift to Sanatorium.—Mr. Jacob H. Schiff, the banker, has given $10,000 to the sanatorium for Hebrew children, Rockaway Park, conditional on the raising of the balance of $25,000 necessary to complete the fund for the erection of a large wing to the sanatorium.

Hospital Dedicated.—The new Washington Heights Hospital, which was opened August 1, was formally dedicated October 15. The hospital is a two-story stone structure. There are at present 32 beds and 12 more will shortly be added. The institution is non-sectarian and will meet the needs of all classes in that district.

Milk Dealers Fined.—A fine of $200, with an alternative of thirty days' imprisonment, was imposed on a wholesale milk dealer in the Court of Special Sessions. It was the fourth offense of which the dealer had been convicted. He was warned that the next time the punishment would be imprisonment in addition to the fine. A number of small dealers were also fined.

Pollution of the Water Supply.—The City Club, corroborating the statements made in the papers in regard to the pollution of the water supply at Mount Kisco, and suggesting as a remedy the condemnation of additional land in that place, has sent a letter to Mayor McClellan urging that immediate action be taken to correct the present abuses, which render water very dangerous.

Lowest Death Rate on Record.—It was announced at the Health Department that the death rate for the week ended October 14 was equivalent to an annual rate of 15.53, as compared with 15.64 for the same week of last year. If figured on actual population instead of the 1900 census, this would be the lowest death rate on record at the Health Department.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended October 14, 302 cases of tuberculosis, with 141 deaths; 219 cases of diphtheria, with 19 deaths; 124 cases of typhoid fever, with 20 deaths; 81 cases of measles, with 5 deaths; 69 cases of scarlet fever, with 4 deaths; 4 cases of cerebrospinal meningitis, with 9 deaths, and 55 cases of varicella.

Personal.—Dr. James F. Donnelly has started for Russia to study cholera and plague.——Dr. H. L. Barnes, Brooklyn, has been appointed superintendent of the State Sanatorium for Tuberculosis, Providence, R. I.——Dr. and Mrs. Florian Krung have returned from Europe.——Dr. Charles T. Schondelmeier has been re-elected president of the Long Island Throat Hospital and Eye Infirmary, Brooklyn.——Dr. Julian Dean was elected a trustee of the institution.

NORTH CAROLINA.

Hospital Opened.—The private hospital of Dr. David T. Tayloe, located near his home in Washington, was opened with appropriate exercises week before last.

Sentenced for Fraud.—Dr. M. Avery, Salisbury, who was heavily fined in the Federal Court for frauds against the government and sentenced to three months in jail, was taken to Salisbury October 7 to serve his jail sentence.

Physicians Prescribe Whisky.—The recorder of Charlotte has inaugurated a campaign against physicians who give indiscriminate prescriptions for liquor. He says that four of the physicians of the city are issuing more prescriptions than the other forty physicians of the city combined.

Medical Schools Opened.—The University of North Carolina Medical Department, Raleigh, opened for its annual session September 14 with an address by Dr. Hubert A. Ryster, dean of the faculty. Dr. Ralph S. Stevens has been added to the faculty as lecturer on pathology.——North Carolina Medical College opened October 3 with an address by Dr. Isaac W. Faison, Charlotte, dean of the faculty.

Ethics in a Nutshell.—The Cumberland Valley Medical Society recently enjoyed a most delightful outing at the country home of Dr. Thomas D. Haigh, one of its veteran members. Picnic refreshments were served and the society entertained and instructed by an address from Dr. Haigh emphasizing the importance of high ideals in the professional life and suggesting that after all the talk about medical ethics the whole scheme is included in the thought and actions of a medical gentleman.

Personal.—Dr. J. Howell Way, secretary of the Medical Society of North Carolina, has returned to his work at Waynesville after a brief vacation spent in the hospitals of New York.——Dr. Edward C. Register, Charlotte, has returned to his home after an extended tour of Europe.——Dr. Richard H. Whitehead, for ten years professor of anatomy in the University of North Carolina at Chapel Hill, is leaving the state to assume the duties of the chair of anatomy in the University of Virginia, to which he was recently elected.——Dr. Robert L. Gibbon, Charlotte, has been elected medical director of the Conservative Mutual Life Insurance Company of that place.

OHIO.

The Afflicted.—Dr. John W. Murphy, Cincinnati, is seriously ill with what is believed to be an abscess of the frontal sinus.

Donation Day.—More than $1,000 was contributed to the German Deaconess Home and Hospital, Cincinnati, at its annual donation day, October 12.

New Dispensary Opened.—The medical and pharmacal departments of Toledo University opened a free clinic and dispensary October 16 at the college building.

Personal.—Dr. Reber F. Quigley, Vermillion, has returned from the Pacific Coast.——Dr. D. C. Clark Hoffman, Dayton, chief surgeon at the Soldiers' Home, has resigned.

Diphtheria Epidemic.—Leetonia is experiencing a scourge of diphtheria which is increasing with such rapidity that the Board of Health has ordered the schools closed until further notice.

Lancet-Clinic Incorporates.—The Lancet-Clinic Company of Cincinnati was incorporated October 16 with a capital stock of $100,000 by Drs. James C. Culbertson, William Ingram, William H. Falls, William D. Haines and Rufus B. Hall, all of Cincinnati.

Physician Vindicated.—Dr. Henry F. Kattenhorn, Cincinnati, who was sued by Ella Doty in 1902 for damages on the charge of having negligently treated a fracture of the arm, was given judgment October 13, as it was shown that the bone alleged to have been broken was not broken, and the one which was broken had been properly treated by the defendant.

PENNSYLVANIA.

New Hospital.—The old Mills homestead, Braddock, is being remodeled as a hospital at a cost of about $7,000.

Practice Without License.—"Dr." Densen, Scranton, convicted of practicing medicine without license, was sentenced to pay a fine of $200 and in default was committed to jail.

Annex for Hospital.—The board of directors for the Mercy Hospital, Pittsburg, decided on the erection of a three-story addition to the hospital, to cost $50,000 and to contain operating rooms, a free dispensary and an amphitheater.

State Hospital Staff Elected.—Dr. Joseph Thomas, Quakertown, has been re-elected president of the board of trustees of the State Hospital for the Insane, Norristown. Dr. Julia Harden, Philadelphia, was elected assistant resident superintendent, and Drs. D. Richardson and Mary M. Wolfe were re-elected to the medical staff.

Help Hospitals.—The Sewickley Af-Fair netted $4,000 to the Sewickley Hospital.——The late Robert L. Shetter, York, devised $5,000 to be used for the endowment of a bed in the Methodist Episcopal Hospital, Philadelphia.——Mrs. Mary L. Baer, Lancaster, has given the Lancaster General Hospital $10,000 for the endowment of a bed in memory of her husband, the late Reuben L. Baer.

Guilty of Malpractice.—In the case of Dr. W. A. Cochran, Easton, charged with criminal malpractice on Miss Lizzie Trader, Phillipsburg, the defendant was found guilty, and is reported to have fled to Canada.——Dr. Edwin S. Cooper, New Castle, charged with conspiring to perform a criminal operation on Miss Mabel Williams of Johnstown, was found guilty September 13. Dr. Cooper was convicted on the same charge two years ago and sentenced to two years' imprisonment, but was granted a new trial.

Personal.—Dr. William R. Palmer, Johnsonburg, was operated on for appendicitis at the Elk County General Hospital September 14.——Dr. John C. Greenewalt, Chambersburg, was thrown from his horse September 24 and dislocated his shoulder.——Dr. Thomas T. Zerbe, Schaefferstown, fell September 19 and fractured a rib.——Dr. A. Barr Snively, Waynesboro, was thrown from his buggy September 17 and fractured several ribs.——Dr. and Mrs. S. Louis Zeigler, Reading, have returned after a three months' tour of Europe.——Dr. Albert C. Snider, White Haven, has been appointed local surgeon for the Lehigh Valley Railway vice Dr. S. Wilson Trimmer, deceased.——Dr. Edward A. Weiss, Pittsburg, was held up and robbed October 2 for the third time in three months.——Dr. Cameron Shultz, Danville, has been commissioned first lieutenant and assistant surgeon, N. G. Pa., and assigned to the Twelfth Infantry.——Dr. Alfred J. Yost, mayor of Allentown, left October 5 for the Pacific Coast.——Dr. William P. Burdick has been appointed surgeon for the B., R. & P. Railroad at Mount Jewett, and Dr. William J. Fredericks oculist for the company at Bradford.——Dr. Elizabeth McLaughry, New Castle, has sailed for Europe.——Dr. Milton Goldsmith and wife, Pittsburg, have returned from Europe.——Dr. Samuel S. Apple, Easton, has suffered the loss of his wife, who died from valvular heart disease October 9, aged 65.

Philadelphia.

College Opens.—The Women's Medical College opened September 27 for its fifty-fifth year.

Von Noorden Entertained.—Prof. Dr. Carl von Noorden, Frankfurt, Germany, was entertained by the Medical Club of Philadelphia, October 25.

Martin Resigns.—Dr. Edward Martin, director of the Department of Public Health and Charities, has resigned. In his letter to the mayor he assigns as reason that the "times are too strenuous."

Coroner's Physician Fined.—Dr. William S. Wadsworth, a coroner's physician, who was a witness in a criminal case, was fined $25 and costs for being late in returning to court after recess. The fine was promptly paid.

Charge Unfounded.—After two hearings Dr. Charles Conrad, who had been arraigned on the charge of conducting a disorderly house, was discharged, the prosecution having been shown to have no foundation in fact.

Chinese Visitors.—Drs. Ho Kan Yuen, fleet surgeon in the Imperial Chinese Navy; Tsui Ying Young, surgeon major in the Imperial Chinese Army, and W. P. Chung of the government hospital service, recently visited Philadelphia.

Suffer for Breaking Laws.—Dr. Thomas Wallace was convicted on September 20 of using the mails for advertising medicine for illegal purposes and was sentenced to pay $100 fine and to serve nine months in the county prison.——Minnie Tilburn pleaded guilty September 28 to performing a criminal operation on Lillia Rentfer and was sentenced to two years in the county prison.

Health Report.—The deaths reported from all causes during the week ended October 21 numbered 308. This is an increase of 30 over the number reported for the previous week, and an increase of 18 over the number for the corresponding period of last year. The principal causes of death were: Typhoid fever, 7; diphtheria, 6; tuberculosis, 42; cancer, 23; apoplexy, 24; heart disease, 42; acute respiratory disease, 32; enteritis (under 2 years), 29; enteritis (over 2 years), 8; appendicitis, 5; Bright's disease, 35; suicide, 3, and accidents, 15. There were 212 cases of contagious disease with 16 deaths, as compared with 171 cases and 12 deaths for the previous week.

Bequests to Charity.—The will of the late John Alter, who died in August last in Vichy, France, devises $50,000 to Jefferson Hospital for the erection of a John Joseph Alter memorial in that institution. The trustees are to decide what kind of a memorial would be most suitable. Bequests of $5,000 are also made for the endowment of two free beds in the above named hospital, together with two beds endowed for $10,000 in the University Hospital.——By the will of the late Susan C. Whelan the Maternity Hospital receives $500.——By the will of the late David Teller the Jewish Hospital Association of Philadelphia receives $200, and the Jewish Foster Home and Orphan Asylum a like sum.——By the will of the late Mrs. Frances E. Loeb the Jewish Hospital Association and the Jewish Maternity receive $500 each.

Portrait of Dr. Coxe Presented to the University.—An oil portrait of Dr. John Rodman Coxe, one of Philadelphia's earliest and most famous physicians, was presented to the department of medicine of the University of Pennsylvania October 20. The presentation was made at the home of Dr. Roland G. Curtin by Dr. Richard A. Cleeman, in behalf of J. Rodman Coxe, a grandson. Dr. Coxe was born in Trenton, N. J., Sept. 16, 1773. In 1790 he began a four years' course of study under Dr. Benjamin Rush. He was port physician in 1798, for five years was connected with the Pennsylvania Hospital, and was also a physician at the Philadelphia Dispensary. In 1809 he was professor of chemistry in the University of Pennsylvania, and from 1818 to 1835 he was professor of materia medica and pharmacy in the same institution. He was a trustee of the university and one of the founders of the Philadelphia College of Pharmacy. The presentation was given added interest by the meeting of the Historical Club of the department of medicine of the University of Pennsylvania at the same time.

Personal.—Dr. Frank W. Talley was thrown out of an automobile in a collision at Allentown September 24 and seriously bruised.——Dr. William H. Semple was seized with hemorrhages while riding on a street car September 16 and is critically ill at the Medico-Chirurgical Hospital.——Dr. Heatley C. Dulles has returned from Europe.——Dr. Judson Deland has returned from a visit to India, where he has been making an especial study of tropical diseases.——Dr. M. Frank Kirkbride and family sailed for Naples October 15.——Dr. Nathan F. Mossell was re-elected medical director and chief of staff of the Frederick Douglass Memorial Hospital. At a meeting of the board of directors it was decided that the election, at a previous meeting, of Dr. P. C. Howard to succeed Dr. Mossell was illegal.——Dr. W. H. F. Addison of the University of Toronto has been appointed demonstrator of histology in the department of medicine of the University of Pennsylvania.——Dr. Francis J. Higgins has been appointed on the out-patient surgical staff of St. Joseph's Hospital.——Dr. Mortimer Herzberg, University of Pennsylvania, 1902, was one of two successful candidates for the positions of assistant bacteriologists of the bureau of health at a recent civil service examination.

SOUTH CAROLINA.

College Opens.—The Medical College of the State of South Carolina, Charleston, opened for its annual session October 2. Dr. Francis L. Parker, the dean, delivered the opening address.

An Ethical Rule.—The Columbia Medical Society has passed a rule strongly condemning the publication of names of any of its members in professional items or news.

Personal.—Dr. Lewis A. Griffith, Columbia, has been elected chairman of the local board of health, vice Dr. E. C. McGregor, resigned. Dr. McGregor was elected vice-chairman of the board.——Dr. David B. Frontis, Ridge Spring, was recently thrown from his buggy in a runaway accident and painfully hurt.——Dr. W. W. Fennell, Rock Hill, has purchased the stock of the other physicians interested in the Rock Hill Hospital.

TENNESSEE.

Graduation Exercises.—The commencement of the medical department of the University of the South, Sewanee, held its annual commencement exercises October 26, when a class of 27 was graduated.

East Tennessee Medical Society.—The fifteenth annual meeting of the East Tennessee Medical Society was held in Bristol September 29. Dr. Charles J. Broyles, Johnson City, was elected president; Dr. Claude P. Fox, Greenville; A. G. Kern, Knoxville, and William A. Dietrich, Chattanooga, vice-presidents, and William M. Copenhaver, Bristol, secretary. The society will meet in Johnson City next year.

Personal.—Dr. John R. Biust, Nashville, was recently operated on for appendicitis at Rochester, Minn.——Dr. James G. Haywood, Memphis, is critically ill.——Drs. John A. and H. C. Murphy, Bristol, have started for California.——Dr. Benjamin B. Cates, Knoxville, has been seriously ill with septicemia.——Dr. James H. McCall, United States Army, has been made a member of the faculty of the medical department of Vanderbilt University, Nashville.

Colleges Opened.—The medical department of Vanderbilt University opened October 2 with addresses by the Rev. G. W. Bull and Dr. G. Chris. Savage.——At the opening exercises of the medical department of the University of Nashville, October 2, Dr. Sidney S. Crockett presided and Dr. R. L. C. White delivered the address of welcome.——The medical department of the University of Tennessee, Nashville, opened for the year October 2 with addresses by the mayor of Nashville and Dr. S. A. Medors, dean of the dental department.

TEXAS.

Operated on for Appendicitis.—Dr. Benjamin M. Warsham, Austin, who was recently operated on for appendicitis in New York City, is making favorable progress toward recovery.——Dr. F. P. Seymour, Beeville, who was recently operated on for appendicitis, has returned to his home.

School Inspection.—The individual medical inspection of the pupils of the city schools of Dallas was inaugurated October 2 by Drs. Robert S. Yancey, Scurry L. Terrell, W. E. Howard, Theo. L. E. Arnold, Martin E. Taber, Frank J. Hall, Benjamin R. Bluitt, Richard T. Hamilton and Edward H. Carey.

Executive Committee Meeting.—The executive committee of the State Medical Association met at Fort Worth October 3 to prepare for the reception and entertainment of Dr. J. N. McCormack, chairman of the Organization Committee of the American Medical Association, who reaches El Paso October 30, and who will make a tour of the state, visiting the various medical societies.

Personal.—Dr. John S. Carter, Denison, is ill with rheumatism.——Dr. James E. Dodson, Vernon, suffered a dislocation of the patella and serious lacerated and contused wounds in a runaway accident September 29.——Dr. Andrew W. Duke, Center, while driving a few miles from town was thrown from his buggy and rendered unconscious for a short time.——Dr. Charles W. Griffith, La Porte, has returned from the Pacific Coast.——Dr. John W. Vermillion, Silverton, has moved to Texhoma, Okla.

Medical Schools Opened.—The fifteenth annual session of the medical department of the State University of Texas, Galveston, began October 2. The opening address was delivered by Dr. William S. Carter, dean of the institution. Dr. M. L. Graves has succeeded to the chair of medicine, vice Dr. James W. McLaughlin, resigned.——The Southwestern University Medical College, Dallas, opened for the first term in its new building October 2.——Baylor University College of Medicine, Dallas, held its opening exercises October 2. The term has been extended from six months to seven months, and entrance requirements have also been increased.——The medical department of Fort Worth University opened for the year September 26. The opening address was delivered by Dr. Frank Gray, dean of the institution.

VERMONT.

Personal.—Dr. Henry D. Holton, Brattleboro, has succeeded Dr. Don D. Grout, Waterbury, as a member of the state tuberculosis commission, and was elected chairman of the commission.

Change in Journal Management.—The *Vermont Medical Monthly* will hereafter be conducted by the following board: Dr. Bingham H. Stone, editor-in-chief; Dr. Henry C. Tinkham, Dr. Charles F. Dalton and Prof. H. L. White, all of Burlington.

Must be Relicensed.—Seventy-eight physicians from different sections of the state, who have been practicing without having their licenses recorded, have been summoned before the state medical board for examination. Included in this number are physicians who have been in practice thirty years, and three of those summoned are members of the faculty of the medical department of the University of Vermont. This action on the part of the board was made necessary by the provisions of a law passed by the legislature in 1904.

State Society Meeting.—The Vermont State Medical Society held its ninety-second annual meeting in Burlington October 12-13, the president, Dr. Patrick E. McSweeney, Burlington, in the chair. The presidential address was on a technical subject, "Tumors Complicating Pregnancy," and the address of the first vice-president was on the subject "The Physician as an Educator." The election of officers resulted as follows: President, Dr. Myron L. Chandler, Barre; vice-president, Dr. Elmore S. Allbee, Bellows Falls; secretary, Dr. George H. Gorham, Bellows Falls; treasurer, Dr. Brigham H. Stone, Burlington; auditor, Dr. John H. Blodgett, Saxton's River; executive committee, Drs. Myron L. Chandler, Bellows Falls; George C. Gorham, Bellows Falls, and Henry C. Tinkham, Burlington; committee on publication, Drs. George C. Gorham, Bellows Falls; George R. Anderson, Brattleboro, and Clarence Beecher, Burlington; committee on [illegible]ur B. Bisbee, Montpelier, and Henry D. [illegible], delegate to American Medical Association, Dr. Carroll B. Ross, West Rutland. A resolution regarding uniformity in fees for physicians was discussed, but no action was taken on it. Resolutions were adopted eulogizing Senator Proctor for his gift of the establishment of a tuberculosis sanatorium, and requesting him to allow his name to be used in connection with the institution. The next meeting of the society will be held in Barre.

VIRGINIA.

Must Report Contagious Diseases.—Failure on the part of many Richmond physicians to comply with the ordinance requiring them to report to the Board of Health the existence of all cases of contagious diseases has compelled the board to instruct the health committee to enforce the rule in this regard.

Personal.—Dr. Stuart McGr[illegible]e first time as president of the University [illegible] at Richmond at the mass meeting of students October 5.——Drs. W. Levi Old and Israel Brown, Norfolk, returned from Europe October 12.——Dr. Marvin P. Rucker, Manchester, has returned from Europe.

Union of Colleges.—Plans for the consolidation of the Medical College of Virginia, Richmond, and the medical department of the University of Virginia, Charlottesville, were discussed by the board of visitors October 6.——Dr. George Ben Johnston of the Medical College of Virginia, Richmond, was elected professor of surgery in the medical department of the university, to succeed Dr. J. H. Buckmaster, resigned, and was also made chief of the staff.

WASHINGTON.

Washington State Medical Association Grateful.—The following is an extract from the proceedings of the seventeenth annual session of this association, held in Tacoma, September 25-27:

> Dr. Semple said: "We have been greatly indebted to the American Medical Association and to Dr. McCormack, who has given his time and talents to assist us in helping ourselves, and I therefore move that the thanks of the Washington State Medical Association be tendered to the American Medical Association for their assistance to us, and Dr. J. N. McCormack for his able and masterly address, giving us his experiences in organizing our profession, advising us of proper methods to increase our influence, better our position and solve the many questions that confront us."

The motion was duly seconded and carried.

WEST VIRGINIA.

Fire Damage.—Fire at Germania September 25, supposed to be of incendiary origin, destroyed the house and office of Dr. W. G. Drinkwater.

Fined [illegible] Liquor.—In the case of Dr. Walter L. Leach, [illegible] with illegally issuing a prescription for whisky, the defendant was found guilty and was sentenced to pay a fine of $50.

Not Guilty.—The charges against Dr. Albert H. Kunst, superintendent of the West Virginia Hospital for the Insane, Weston, were proven on investigation to be absolutely without foundation, but Dr. Kunst has handed his resignation to the board of directors, to become effective January 1.

WISCONSIN.

Addition to Hospital.—The extensive addition to the Deaconess Mother House of the Milwaukee Hospital has been completed. The building will be used for offices, assembly rooms and dormitories.

Little Contagious Disease.—The Milwaukee Isolation Hospital is empty; since June there have been 215 cases of smallpox, with 1 death. The city is reported to be unusually free from communicable diseases.

Jail for Spitters.—An ordinance introduced in the Sheboygan city council October 17 provides a jail sentence for violations of the anti-spitting law, and owners of theaters and public halls are notified to provide sufficient cuspidors or suffer penalty.

College Opens.—The Milwaukee Medical College opened for its twelfth annual session October 3. The opening address was made Dr. William H. Earles, president of the institution. Dr. E. L. Bullard has been made professor of nervous and mental diseases.

Personal.—Dr. J. Fremont Corbett and wife, Weyauwega, have moved to Southern California.——Dr. Daniel W. Lynch, West Bend, and Dr. Grove Harkness, Waukesha, have returned from the Pacific Coast.——Dr. and Mrs. Arthur J. Patek have returned after a summer in the Adirondacks.

Chiropractic Fined.—In the case of the state of Wisconsin against G. W. Johnson, La Crosse, for practicing medicine without a state license, the court found that the defendant had not treated patients. The case against him was, therefore, dismissed and a warrant issued for his partner, E. J. Whipple, on whom devolved the duty of treating patients. Whipple was found guilty October 12 of practicing medicine without a license and was sentenced to pay a fine of $50 and costs, making the total judgment about $100. The defendant asserts that he will appeal the case.

GENERAL.

Experiments with the Milk of Malta Goats.—It is reported that the Department of Agriculture is to experiment in typhoid fever with the milk of goats recently imported from Malta. The goats were subjected to a rigorous quarantine and have been careful ly inspected to determine their freedom from Malta fever.

Cholera in the Philippines.—A cable report from the Philippines states that cholera is practically wiped out. From August 23 to October 14 there were 713 cases and 553 deaths. In Manila the cases and deaths are thus classified: Americans, 11 cases and 6 deaths; Filipinos, 180 cases, 162 deaths; foreigners, 19 cases, 15 deaths; Chinese, 4 cases and 4 deaths.

Physician for Indian Service.—The United States Civil Service Commission announces an examination Nov. 22, 1905, to secure eligibles from which to fill a vacancy in the position of physician (male), at $1,000 per annum, San Juan Indian Agency, N. Mex.; another, at $900 per annum, at Fort Bidwell, Cal., and similar vacancies as they may occur in the Indian service. As the commission has experienced considerable difficulty in securing eligibles for this position, but five having been secured as the result of the examination held on Sept. 13, 1905, qualified persons are urged to enter this examination. This examination is open to all male citizens of the United States between the ages of 25 and 55. Applicants should at once apply either to the United States Civil Service Commission, Washington, D. C., or to the secretary of any civil service board of examiners, for application form 1312.

Yellow Fever News.—Except at Pensacola the epidemic is practically at an end.——At New Orleans there was a final general fumigation on October 15.——The steady decline in the number of new cases has continued.——On October 17 it was announced that the Emergency Hospital at New Orleans would receive no more cases.——On the same date eleven acting assistant surgeons who had received local appointments were released.——On October 22 there were only two new cases reported in New Orleans and no deaths.——All Mississippi quarantines were raised on October 23.——Texas has raised its quarantine except as against infected points.——At Pensacola the epidemic is yet active, due wholly to the fact that a large element in the population will not co-operate in fumigation and other sanitary measures, especially the reporting of cases.——Castleberry, Ala., has had two cases of yellow fever, the infection coming from Pensacola.——Georgia has extended its quarantine to include several Alabama counties.——Knoxville, Tenn., has discontinued train inspection.——Arkansas has modified its quarantine only slightly.——Cincinnati has discontinued its recently established train inspection system which employed thirty physicians.

Cholera in Manila.—During the week ending September 2 there were 70 cases of cholera in Manila, with 56 deaths. During the following week, according to *Public Health Reports*, there were 78 cases, with 69 deaths. The first cases of cholera were of the most virulent form. Those who were attacked succumbed in a few hours, and all had the type ordinarily described as cholera sicca. The disease has not shown a tendency to localize itself in any one portion of the city, and, so far, there has been no second case to appear in any house in which the disease has been discovered. This would indicate that the disinfecting measures which are being practiced have been effective. Those portions of the city which are the most crowded, and in which the so-called "slum" population resides, so far have been but slightly invaded. In fact, the disease has appeared sporadically in every portion of the city, and the persons who have been attacked up to the present time have been generally of the better classes. So far, there have been 7 Americans (?) attacked, with 3 deaths; also 6 Europeans, and, in proportion to the population, there have been more cases among the Americans and Europeans than among natives. There is as yet no exact evidence as to where the disease started. It is known, however, that cases occurred in Taguig and Pateros, which are small villages near Lake Laguna in the interior of Luzon, at least one week before the disease was found in Manila. Numerous theories have been advanced as to its origin in these places, but no satisfactory conclusions have been reached. Among others is the fact that the body of a person who died of cholera was exhumed at Pateros shortly before the outbreak. Another is that possibly the conditions of some of the wells near Pateros are such that cholera germs may live in them indefinitely, and, at times, for some unknown reason, assume a virulent form. Many medical men of the islands are now inclined to believe that the disease is indigenous to the Philippines. One point has been observed which should receive consideration by laboratory workers, and that is that for some time before the outbreak persons died with all the clinical symptoms of cholera, and on postmortem examination the bodies presented the gross pathologic lesions of the disease, but no organisms were found at the bacteriologic examinations which were made. The quarantine of interisland vessels has been continued, and it is hoped that it will be effective at least in preventing the spread of the disease to other islands. Army medical officers outside of Manila are co-operating with the Public Health and Marine-Hospital Service in maintaining a quarantine inspection of vessels. Major-General Corbin has tendered the services of such army medical officers for this purpose as may be spared. In view of the experience gained in the last cholera epidemic it was not deemed advisable to institute a land quarantine or to place a cordon around the city of Manila or other infected districts, because the lay of the land is such that to make such a quarantine effective at least 100,000 men would be required. The fact that no such rigid measures have been adopted has been of the greatest assistance to the board of health in gaining the co-operation of the natives. So far this course has been fully justified, because the disease has not spread to the provinces with anything like the rapidity with which it did in the former epidemic. The only places outside of Manila at which cases have occurred are Pasig, Taguig, Pateros, and Jala Jala in Rizal Province, Malabon in Bulacan Province, and Guagua and San Fernando in Pampanga Province. So far, the total number of cases in the provinces has not been as great as that in Manila. The policy of the insular board of health has been to combat the epidemic by a campaign of education rather than by rigid measures. Circulars are being sent out by the bureau of education with instructions that the teachers in the schools in every town and village throughout the Philippine Islands shall teach the contents to their pupils. The board of health likewise sends them to all its officials located in all parts of the islands. In addition, the various religious orders are also sending out the circular with the request that its contents be diffused among the people.

CANADA.

Health of Montreal.—In Montreal during the week ending October 14, 21 cases of diphtheria were reported, 8 of typhoid fever and 12 of tuberculosis. The total mortality during the week was 85, and there were 66 births.

Tyhoid Fever in Winnipeg.—There is an alarming epidemic of typhoid fever in Winnipeg. There are said to be 334 cases in the two hospitals. The attention of the Manitoba Board of Health has been directed to the matter and Drs. Gordon Bell and R. M. Simpson are making an investigation into the causes of the epidemic.

Medical Organization in Lower Canada.—The physicians of Wolfe County, Canada, have organized and held their first meeting in September. Dr. A. Thibault of Wolton is honorary president, and P. Chicoine of Israeli, acting president. A general rate for fees was adopted, and a motion presented to the effect that the secretary correspond with the secretaries of other medical associations to agitate the following proposition, viz.: That the physicians of said association guarantee to cast their vote against every member of congress who works for the passage of a private bill licensing any irregular, unless the said bill has first been approved and recommended by the "Collège de médecins et chirurgiens de la province de Quebec." The *Bulletin Méd. de Quebec* for September contains the detailed account of the proceedings.

Personal.—Dr. Claude Freeman, formerly superintendent of the Hamilton (Ont.) City Hospital, has gone to China, where he will be assistant to Dr. McCartney, superintendent and surgeon of the General Hospital at Chung King, province of Sze-Chuan.——Dr. J. H. Bell, ex-mayor of Kingston, Ont., has been appointed health officer of that city in succession to the late Dr. Fee.——Dr. Charles Elliott of London, Ont., will go to China as a medical missionary at the end of October.——Dr. George D. Porter, Toronto, has gone abroad for a year's postgraduate work.——Dr. Halden Love, late of Carlton Place, Ont., but now of North Dakota, has lost the sight of both eyes through a gunshot injury, and as a consequence has given up the practice of medicine.——Dr. Nickle of Mather, Man., has succeeded to the practice of the late Dr. George Riddell of Crystal City, Man.——Dr. Mulvey of Minto, Man., has been taking a postgraduate course in Chicago and will locate in Crystal City, Man.

Hospital News.—The total number of patients treated in the General Hospital, Winnipeg, during the week ending October 14 was 379, of whom 262 were men, 76 women and 41 children. In the outdoor departments the number treated was 103.——At the beginning of September there were 60 patients in the Vancouver General Hospital; 60 were admitted during the month; 49 were discharged cured, 7 died, and there were left in the hospital September 30, 64 inmates.——The estate of the late Hart A. Massey, Toronto, has donated $100,000 to the Toronto General Hospital. This gift now brings the available amount for the new hospital up to $979,000. The total amount required for the project is $1,200,000 to $1,400,000.——Mr. Thomas McCormack of London, Ont., has made arrangements to erect a handsome seven-roomed cottage on the grounds of the Muskoka Cottage Sanitarium. The expenditure for this purpose will amount to $6,000.——The Victorian Order of Nurses in Canada does work in 16 districts and has 17 hospitals, where over 6,000 patients have been treated.

FOREIGN.

Yellow Fever in French Guiana.—It is reported that 2 cases of yellow fever have occurred at one of the convict stations on the Maroni River.

Plague in China.—The American consul general in Niuchwang reported October 12 that cases of plague had occurred in that city with one death. The disease is supposed to have originated in Antung. Traffic in the interior is temporarily interrupted.

Cholera in Europe.—The *St. Petersburg. Wochft.* states that it has been officially announced that 27 cases of cholera were reported in Russia between September 1 and 10, with 17 deaths. The cases were scattered through three districts, Warsaw, Lodz and Lomsha.

Monkeys for Neisser.—A hundred monkeys of all kinds and sizes have been embarked at Singapore en route for Breslau, destined for Professor Neisser's experimental work in inoculation of syphilis. They have been ordered by the German government and include some just caught and others that have already been domesticated by the Malays as shown by the earrings they are wearing. Neisser is still in Java, but he will soon follow this consignment.

Italian Prize Awarded to Vulpius.—The international "King Humbert" prize of $500 for the best work or the best discovery in the domain of orthopedic surgery during the last five years was awarded this year for the first time. The recipient was Prof. O. Vulpius of Heidelberg, Germany, for his work on the transplantation of tendons to relieve paralyses. The prize money has been presented by Vulpius to a home for cripples now being erected in Baden.

Medals Presented by Tuberculosis Congress.—The newly endowed "tuberculosis medals" were awarded at the closing session of the Tuberculosis Congress at Paris. The two gold medals were given to Robert Koch of Germany and to Paul Brouardel of Paris. Silver medals were given further to Billings of New York, Bang of Copenhagen, Broadbent of London and von Schroetter of Vienna. It was officially announced the next congress will be held in this country in 1908.

Another Russian Medical Congress in Trouble.—The Congress of Russian Psychiatrists met at Kiev in September, with Professor Ssikorski in the chair. About 130 members assembled, but at one of the meetings a large crowd of students and others gathered outside and demanded entrance. They at once proceeded to turn the meeting into a political demonstration, demanding the release of certain persons who had been recently arrested by the authorities. The president had to summon police aid and adjourn the congress.

Cholera in China.—Acting Assistant Surgeon Ransom reports from Shanghai that he has learned from a fairly reliable source that there were about 400 deaths in that city from cholera of natives in one guild (society), which has a membership of about 200,000, though at present the disease seems to be in abeyance. Dr. Ransom states that there were probably about 600 deaths from this disease during July, August and September, and that this has been an exceptionally healthy year, so far as cholera is concerned.

Plague and Cholera in India and Burmah.—In India during the week ended Aug. 26, 1905, there were 2,873 cases of plague, with 2,050 deaths, and during the week ended Sept. 2, 1905, 3,157 cases and 2,330 deaths. It is reported from Rangoon that the destruction of rats was continued with unabated vigor during August. During that month 13,128 rats were destroyed. Total number of rats killed since February, when the epidemic commenced, to the end of August, 142,985. Acting Assistant Surgeon Eakins reports that during the week ended Sept. 2, 1905, there were 28 deaths from cholera and 11 deaths from plague, and during the week ended Sept. 9, 1905, 34 deaths from cholera and 15 deaths from plague in Calcutta.

Hospital for the Blind in Porto Rico.—An asylum for the blind was opened at Ponce, P. R., the beginning of October. It was dedicated by Governor Winthrop and the Stars and Stripes were raised over the building by Mrs. Winthrop while a native band played "The Star Spangled Banner." The building, with its modern furnishings, is worth $40,000, and is on an excellent site on a hill overlooking Ponce and the Caribbean Sea. The furnishings are from the United States throughout. As the work expands the capacity will be enlarged. The legislative assembly of Porto Rico has provided for maintenance of 150 inmates and 30 employes for the present fiscal year. It is a noteworthy fact that every officer and employe of the new asylum is a Porto Rican. It will be at the start both a hospital and a home. The most urgent cases from the various municipalities will first be selected and by degrees as the cures are effected, the demand for a hospital of this class will diminish and more importance will be given to its character as a home for the incurable.

Official German Report on Relations Between Human and Bovine Tuberculosis.—The Imperial Board of Health of Germany has given out for publication the report of the committee which has been studying during the last two years, under governmental auspices, the relations between human and bovine tuberculosis. The committee distinguishes two types of tuberculosis in warm-blooded animals, the tubercle bacilli of fowl tuberculosis and the tubercle bacilli of mammal tuberculosis. The tubercle bacilli of mammal tuberculosis can be further classified as the human and the bovine. From one to two years of experiments and tests failed to show any indications of transformation of any one of these types into another type. The attempts to inoculate cattle with human tuberculosis all resulted negatively. Nine cases of tuberculosis of the bovine variety were discovered among 67 persons with tuberculous lesions, and in 2 both types of bacilli were found. The bovine cases were all in children under the age of 8, and in 6 of the cases infection had evidently been by way of the intestines. In 2 cases the lesions were in the neck. The bovine tubercle bacilli were found in or near the entering point of the bacilli or in the glands near by. The bovine bacilli cultivated from the human lesions showed no differences in any respect from those cultivated directly from cattle. The report further states that tuberculosis in cattle was found to be caused by bovine tubercle bacilli from cattle or other domestic animals, man being also liable to be a source of infection in the rare instances when affected with tuberculosis of the bovine variety. Pigs are susceptible to both bovine and human tuberculosis infection, but the disease in swine is almost invariably of bovine origin. Feeding swine with swill from dairies is an important source of their infection with bovine tuberculosis. Tuberculosis in other domestic animals is generally traceable to infection from cattle. In poultry tuberculosis is due to infection with the tubercle bacillus specific for fowls, and this plays no part in the spread of tuberculosis among human beings. In man tuberculosis is generally due to infection with human tubercle bacilli. Infection occurs mainly by transmission from man to man, but there is also a possibility that it may be transmitted by pork from swine infected with human tubercle bacilli. The fact that bovine tubercle bacilli are sometimes found in human tuberculous lesions shows that the human body is capable of infection from the secretions, excreta or meat of tuberculous domestic animals. As a rule, the action of the bovine tubercle bacilli in man is limited to a pathologic process at the portal of entry and the adjacent glands, or in the latter alone, but cases are known in which the process has become general and fatal. The report concludes by pointing out the danger of infection from milk and meat from tuberculous animals unless the bacilli are killed by heating. The report is published in full in the *Deutsche med. Wochft.*, October 5. It is signed by H. Kossel and R. Weber. The former is now professor and director of the Institute of Hygiene at Giessen; both are experts in the service of the imperial Board of Health. Kossel delivered one of the main addresses in the section of surgical pathology at the recent International Tuberculosis Congress at Paris, his being the third address on the subject of "Comparative Study of Various Tuberculoses."

The Communication of von Behring to the Tuberculosis Congress.—At the closing session of the congress von Behring announced that in the course of the last two years he had established the existence of a curative principle entirely different from the antitoxic principle. It is the essential element, he stated, in the *immunizing action* of the vaccine with which he has been successfully combating bovine tuberculosis. Four years of experience have demonstrated the efficacy of the bovovaccine, and it is being applied now on a large scale in agricultural circles. "The curative principle," he continued, "depends on the impregnation of the living cells of the organism with a substance derived from the virus of tuberculosis, which I call TC. When the TC has become an integral part of the cells of the organism of the animals treated with it, and has become transformed by these cells, I designate it as TX. In the bacillus of tuberculosis the TX, or, rather, the TC preexist as an agent endowed with a large number of extraordinary properties. In the bacillus this agent has the function of a formative substance. It has also fermentative and catalytic properties. It can fasten itself by contact on other substances—a phenomenon called 'adsorption'—and has assimilating properties, in short, it represents the 'quasi vital principle' of the bacilli. In cattle, in the process of rendering them immune to tuberculosis, the TC is freed from accidental substances. It exerts a symbiotic action inside the cells of the organism, especially in the cellular elements which are derived from the germinal centers of the lymphatic tissue. The presence of the TC is the cause of the supersensitiveness to Koch's tuberculin, on one hand, and of the protecting reaction against tuberculosis, on the other hand. This conception of a cellular immunity is entirely different from the antitoxic humoral immunity." The Journal of Oct. 17, 1903, page 994, presented Behring's announcement in regard to vaccination of cattle against tuberculosis. (See also page 620 of volume xlii.) His experience has convinced him that the technic was inapplicable to man, it being unwise to inject live tubercle bacilli into human beings for therapeutic purposes. He continued, in his congress address: "The discovery of this curative principle is destined, I believe, to protect human beings threatened with phthisis against the injurious action of tuberculous infection. As I studied it more and more I found that the relations between vaccination and immunity became plain, and that it solved one after another of the puzzling problems in regard to the nature and mode of action of antidiphtheria serum. After the discovery of the curative principle my efforts were directed to produce it *in vitro* and thus spare the cells of the organism the arduous and sometimes dangerous task of elaborating the TX under the influence of the TC. This I have accomplished, substituting passive immunization for the active immunization of my bovovaccine. The TC has to be freed from the substances which interfere with its therapeutic action. There are three groups of such substances in the body of the bacillus. The first is a substance which has a fermentative and catalytic action and is soluble in water. The toxic elements in Koch's tuberculin are derived from this substance. It possesses all the physical, chemical and tinctorial properties of volutin, and I call it TV. A single gram of this substance in the dry form is more powerful than a liter of Koch's tuberculin. The second substance is soluble only in a neutral salt, such as a 10 per cent. saline solution. I call this substance TGL, as it is like globulin. The third group includes various non-toxic substances, soluble only in ether, alcohol, chloroform, etc. After the bacillus has been freed from these three groups of substances it still retains its shape and staining properties, but it can be modified into an amorphous substance which is absorbed by the lymphatic cells. The amorphous substance is elaborated and metamorphosed by these cells and they become oxyphile and eosinophile. Parallel with this transformation of the cells under the influence of the amorphous substance, the TC, the organism acquires the condition of immunity. One of the fundamental facts is that while the TC is not capable of reproduction, it yet has the power of inducing the formation of the tubercle. The tubercle thus created never undergoes caseation and never softens. It corresponds exactly to 'Laennec's tuberculous granulation.' In certain conditions the TC may also induce gray or gelatiniform infiltration." In conclusion, Behring recalled that four years elapsed after his communication in regard to antidiphtheria serum before the profession at large accepted it. Its acceptance was hastened by Roux's cordial backing, and he hopes that he may be fortunate enough to obtain such a friend for this new remedy, with as much conquering force and the same disinterestedness above all suspicion. He intends to publish a book next year with the title "Modern Phthisiogenetic and Phthisiotherapeutic Problems Illuminated by History." He remarked in regard to it: "The part of the work devoted to the therapeutic aspect of the question will not appear until the therapeutic efficacy and harmlessness of my new remedy shall have been demonstrated by clinicians better versed than I am in the knowledge of the individual varieties of pulmonary phthisis and its prognosis." . . . "I hope that all the scientists to whom I shall entrust my remedy, after my return to Marburg, for them to try it on animals, will obtain in their laboratories as good and even better results than my own."

LONDON LETTER.

How to Combat Consumption.

In a letter to the *Standard* Dr. Tolniewski advocates a modification of the method of combating consumption which is in vogue on the continent. The discussion on the subject, he thinks, should not be confined to the medical press. There are at present in Great Britain 200,000 poor consumptives and about 1,000 beds for them, which means that only 1 in every 70 can be treated per annum. The annual cost to the nation from tuberculosis amounts to $150,000,000, and the cost of relieving the pauperism resulting therefrom amounts to another about $5,000,000. Would it not be wiser, he asks, to spend this sum in curing the patient than in relieving the pauper? The most simple and effective way to do this would be to organize in all the urban centers special dispensaries for the prophylaxis of tuberculosis. The principal mission of these dispensaries would consist not only in giving free consultations and medicine, but in attracting and detaining poor consumptives or those suspected of consumption, giving them food, clothes, etc., when they are obliged to interrupt their work, disinfecting their homes, washing their linen, and sending to sanatoriums those requiring special treatment. The mistake has been made of erecting palatial sanatoriums at great expense while the much less expensive special dispensaries have been neglected. Often it will be necessary not only to treat a patient medically, but to provide him and his family with the necessaries of life, and to rectify the hygienic conditions of his home. The means of assistance might be classified as follows: First Class.—Those receiving meat, coal, milk, bread, vegetables, eggs and part of rent. Second Class.—Those receiving milk, bread, meat, eggs, vegetables and 5 shillings a month toward rent. Third Class.—Those receiving milk and eggs. Under this plan the budget of a dispensary which assisted annually 500 consumptives, cured one-fourth of them and improved the health of more than half the others, without many of them ceasing their daily work, would be considerably less than that of a sanatorium with 50 beds.

Pharmacology

Secret Proprietaries and Prescription Writing.

There is a vast and ever-increasing number of so-called "ethical preparations" with fanciful names, samples of which, with much seductive literature, are poured into every physician's office, and which he is assured by the silver-tongued detail man will be just the thing for this or that obstinate case, which the physician happens to have on hand. The sample is made use of, perhaps the patient feels better the next day, and the physician continues to use the preparation until another remedy takes the place of the first. It is so much easier to write for the proprietary by its euphonistic, and perhaps easily remembered name, than to write a prescription, that many physicians use nothing else in their practice; and then, too, there are many physicians, particularly among the recent graduates of some of our best medical schools, and this is the point we would particularly emphasize, who can not write prescriptions at all. The Minnesota State Board of Medical Examiners, doubtless other state boards have had the same experience, have observed during the last few years many candidates who passed excellent examinations in the other branches displayed hopeless ignorance in their answers to questions concerning materia medica, and particularly concerning prescription writing. There is evidently something radically wrong in the teaching of materia medica in our medical schools, and it is quite time for a radical change in these methods. There should be regular, systematic drilling in prescription writing, even if the time for this work must be found at the expense of some of the more spectacular instruction, in, for instance, major surgery, which the students now receive. The subject of prescription incompatibilities, which now receives but little attention, should be made much more prominent, and we would also suggest that a few practical lectures and demonstrations on the subject of proprietary remedies would be of great value. Let the students, for instance, be taught that "antikamnia" consists of acetanilid, 68 parts; caffein, 5 parts; citric acid, 5 parts, and bicarbonate of soda, 20 parts, and that it costs but a few cents an ounce. They will not then be so likely to make their patients pay a dollar for what the druggist can dispense for 25 cents. Let the other fashionable proprietaries be discussed in the same manner—the Council on Pharmacy and Chemistry of the American Medical Association is rapidly accumulating the material for such teaching—and we feel sure that those who graduate in medicine, having had these facts impressed on them, will not prescribe proprietary remedies, except in those cases where they have good reason to believe that the proprietary is the best thing to prescribe.—*St. Paul Medical Journal.*

The Propaganda Against "Patent" "Proprietary" Medicines.

Of course, our readers realize the fact that a propaganda is being conducted against the "patent-medicine" evil of this country, and that those who are making fortunes out of this traffic in human health and life are thereby greatly agitated. The leaders in the protest against "patent medicines" are the *Ladies' Home Journal*, and *Collier's Weekly*. There are influential laymen quietly but effectively aiding the cause, but, we are sorry to say, physicians are not assisting as they should. This, however, is another story.

The "patent-medicine" men and the makers of proprietary remedies are united in an organization known as the Proprietary Association of America, and the fact that the majority of the manufacturers of these remedies are among its members is sufficient to know that it is a power as far as dollars and cents are concerned. This association is using every effort to stem the tide, and one way of doing it is to influence public opinion.

Recently Mr. J. A. Patten of the Chattanooga Medicine Company—manufacturers of Wine of Cardui, etc., and who was announced as representing the Proprietary Association, delivered an address before the Tennessee State Pharmaceutical Association, which was a defense of "patent medicines." This address has appeared, either in full or in abstract, in newspapers all over the country, but especially in the South.

On reading this address one will be impressed with the fact that the "arguments" sound familiar; that they have been heard before. And sure enough they have been, for are they not the same that the secret "proprietary" manufacturers use and that appear so often in medical journals which defend the prescribing of proprietary medicines? Of course, they—the manufacturers and so-called medical journals—do not defend "nostrums," but secret proprietaries. Incidentally, and in parentheses, we have always been at a loss to know how to distinguish between a secret "proprietary" and a "patent medicine." Reading Patten's address we are still more at sea, for he calls the class of medicines he defends "proprietary."

We quote from the Mobile (Ala.) *Register* and take the liberty of interjecting a word here and there to point a moral as well as to adorn the tale. In other words, we apply Mr. Patten's remarks to the question as it relates to so-called proprietary preparations and to physicians:

> "Mr. Patten said that he felt inclined to speak a few words about the so-called 'patent-medicine curse,' inasmuch as we have recently had unusually severe and persistent attacks on the manufacturers of proprietary [patent] medicines from influential publications and prominent medical organizations. He said one widely circulated paper [*Collier's Weekly*] had gone so far as to state that these manufacturers and the newspapers were in a 'criminal conspiracy' to defraud and poison the public." . . .
>
> "We first observe that it is not from the public [medical profession], the great mass of people [physicians] who use medicines, that these criticisms arise. Note the source from which they come, and the self-appointed guardians appear for a competent people [physicians] who have not asked for such protection."

How very, very familiar this sounds.

> "It must also be admitted by fair-minded people [physicians] that every *self-interest* of the manufacturer prompts him to put out a remedy which is not only meritorious, but safe. However unscrupulous he may be at heart, common sense teaches him that only as he produces an article that will 'repeat'—which will meet the needs of the people who buy it [physicians who prescribe it]—can he reach success."
>
> "Admitting that there are fakes in medicine as in every other line of trade, is it not true that the leading proprietary [he means 'patent'] medicines that have stood the test of time are of known therapeutic value? Are they not prepared in laboratories of the highest grade, under the care of skilled pharmacists, and made from approved formulas, which in many instances have been the especial pride and specific of some successful physician or chemist? [This does *not sound so familiar*.] Have they not been tried in the crucible of public opinion and been found satisfactory by the people [physicians]? For otherwise would not the people [physicians] discontinue using them? Are they not generally obtained at a mere fraction of the cost of the same class of medicines when obtained through a physician's advice and prescription? Are not the millions of people [thousands of physicians] who use them satisfied?"
>
> "Then there is the *formula bill*. This makes it necessary for every proprietary [patent] medicine house to print the formula of the medicine on the label. With no real benefit to the public [med[illegible] ould open the door to a flood of imitator[illegible] l endeavor to profit by the advertising and [illegible] nator of the real formula. It would do th[illegible] ssion] not one atom of good and only resul[illegible] *of trade* conditions, besides making it po[illegible] teal the stock in trade of an honest manufacturer. [The same old argument.]
>
> "In all I have said in speaking of proprietary medicines, I do not refer to the 'fake' *concoctions* of cocain or other admittedly harmful drugs or 'booze,' put up in the guise of *bona fide* remedies. They are no more proprietary medicines than counterfeit bills are real dollars."

This sounds natural, too. Any manufacturer of secret preparations, whether these be "patent" medicines or "proprietaries," will acknowledge that there are some of these remedies which are not good and which should not be used."

We heartily recommend this address by the manufacturer of Wine of Cardui to the secret proprietary manufacturers of the United States and to the medical journals which defend them. The foregoing quotations—we have only space for a few samples—will show how easily this address might be modified so that it could be used as "literature" to convince physicians that the use of secret proprietary medicines is all right.

In this connection, it might be interesting to know what the Chattanooga Medicine Co. manufactures and their manner of advertising. So far as we can learn, their chief product is "Wine of Cardui," and the following advertisements from daily papers which are supposed to be reputable and which are received in the homes of respectable people will indicate what it is:

> But, as we have stated, it is the *weak* woman who suffers such fearful pains at childbirth. Perfectly sexed, strong, healthy women don't.
>
> The Indian mother, on the trail, stops for an hour or so by a river or creek, and then starts on with the new papoose on her back to catch up with the rest of the tribe, which has not even delayed its march to await her.
>
> It is possible for you to build up your female organs, functions and constitutions, to such a state of vital, hearty health, that the Crown of Womanhood will come to you, without its Cross or Thorns.
>
> To accomplish this by natural methods treat yourself with Wine of Cardui, the scientific, specific, health tonic for women.
>
> Cardui, a pure extract of medicinal herbs, exerts a natural, restorative action on the weak female functions, regulates all irregularities, relieves periodical pain, restores falling womb by strengthening the womb muscles, and revitalizes the entire female constitution.
>
> In 70 years it has relieved the sufferings of over a million women.

Here is another advertisement clipped from a current daily newspaper:

> The best wife is a good chum or companion, and in the right wife before age and beauty comes health, or in the power and beauty of superb womanhood man finds his best mate. A well-sexed woman wins success also in business, literary or social life—where the weak-sexed one fails. What is your chance for success or happiness in married or other spheres of life? Are you a victim to any of the many forms of disease peculiar to women, which *prevents you from tasting* to the full the enjoyment and happiness that is due you? If so, cure yourself. It can be done at home, by simple, safe and reliable means—by taking Wine of Cardui, the successful tonic for sick women. . . . Cardui relieves periodical pain, *pulls up falling womb* [italics ours] and builds up health tonicity. Over a thousand women a month testify to its curative powers. Are they all mistaken?

Here is an advertisement from the *Chicago Tribune*:

> The knell of health is tolled for many a poor woman when she enters the married state. Thousands write: "Have not seen a well day since." The manifold duties of married life are too hard for most weak women, but relief is easily obtained by just taking Wine of Cardui. Has cured a million women. No other medicine in the world has done so much good to sick women as Cardui. It relieves pain. Remember, this is the *medicine* you have heard so much about. It will restore your health as it has restored health to a million others. Ask for it. Get it. Take it.
>
> Every druggist sells Cardui in $1.00 bottles.

Pharmacology and Therapeutics of To-day.

The lay public has, for a long time, regarded the dictum of the medical man as authoritative, and even if an *occasional* cavil arises, it is individual and not general. Indirectly, the profession itself is responsible for the abuse of the general public by proprietary and patent medicine concerns. Any druggist will corroborate the statement that the bulk of his stock of proprietary medicines is kept for the physician's prescriptions, rather than for dispensing to the demands of ordinary counter trade. The neglected shelves of most doctors' offices are full of an assortment of these things, and if the public were not first reached through the medical profession, a regular staff of detail men would not be employed and salaried. When even the highest medical office in the gift of the profession is employed *to exploit* a proprietary medicine, even if a mild apology did follow, it argues the value the manufacturer places on such indorsement. And the evil grows. Every one of these compound proprietary preparations carries reports in abstract or out-and-out indorsements, signed by the physicians themselves, often men of recognized authority in their own communities. Of course, the encouragement to further traffic in the medical man's gullibility follows.

These are the conditions as they exist. It requires only a short step for the remedy, accepted by the physician, to be popularized.

The essential factor in all this is much more radical. The fault lies in the training of the medical man himself. It is not far from the mark to say that *nine-tenths* of the graduates in medicine know little or nothing of pharmacology. Prescription writing is acquired slowly after practice is begun, and the vast majority of *young* doctors copy prescriptions of older men, or follow those printed in the texts.

The struggle of the medical student, after his degree, discounts all interest he may have in acquiring any of the elements of a medical education not required in the curriculum. Most medical schools either openly omit all teaching of pharmacy and pharmacology, or else devote a casual lecture or two to expounding the elements. The United States Pharmacopeia is practically unknown to the average medical student and physician, and original prescription writing is as lost an art as Damascene blades.—Editorial in *New Orleans Medical Surgical Journal*, September, 1905.

Work of the Council Indorsed.

At the recent meeting of the Michigan State Medical Society the following resolutions, presented by Dr. H. O. Walker, Detroit, were adopted:

Whereas, Last year the Michigan State Medical Society urged the American Medical Association to provide means for determining the exact composition of medicinal supplies of proprietary substances, in general use, and for publishing the same:

Whereas, Said American Medical Association has established a "Council of Chemistry and Pharmacy" for this purpose, composed of persons both competent and trustworthy;

Whereas, The results already published, foreshadow the great importance of the work, as indicated by the approval of friends, and howls of those fattening on the ways "that are dark" in pharmacy;

Resolved, That the thanks of the Michigan State Medical Society be extended to the American Medical Association for putting into practical operation its request, at so early a date, and in so admirable a manner.

Resolved, That we urge the Council to push its studies of medicines of unknown composition, as rapidly as possible, and to publish the same, that the individual doctor may better know his tools, that medical journals may have a correct standard in regulating their advertising pages, that honest, open pharmacy may be encouraged, and that outsiders may be attracted to organizations which thus are trying to help them in their work.

At its recent meeting in Atlantic City the American Pharmaceutical Association adopted the following resolutions:

Resolved, That the American Pharmaceutical Association, in general session assembled, commends all proper efforts on the part of the American Medical Association to differentiate between the various so-called proprietary remedies with a view of correcting the abuses at present existing in connection with the advertising pages of medical journals.

Resolved, That a copy of these resolutions be forwarded to the secretary of the American Medical Association.

Marriages

De Mott Ryan, M.D., to Miss Iva Ballou, both of Virgil, N. Y., October 4.

Daniel E. Cullers, M.D., to Mrs. Ida Long, both of Stella, Mo., October 4.

E. Van Hood, M.D., to Mrs. Louisa B. Porter, both of Ocala, Fla., September 30.

R. B. Stafford, M.D., to Miss Angie Ewing, both of Walnut, Kan., September 27.

Harry A. Jacobs, M.D., to Miss Naomi Marer, both of Indianapolis, October 11.

Otis T. Wingate, M.D., to Miss Mayione E. Astley, both of Philadelphia, October 18.

Henry H. Kapp, M.D., to Miss Rosa Hege, both of Winston-Salem, N. C., October 11.

Frank L. Gilbert, M.D., Grafton, Vt., to Miss Elva Mack of Windham, Vt., October 4.

Irving J. Fisher, M.D., to Miss Gertrude Hall, both of Somerville, Mass., October 6.

William H. Slattery, M.D., to Miss Florence Marr, both of Lincoln, Neb., October 10.

Perle Clifton Irwin, M.D., Gibson, Iowa, to Miss Mabel Almira Blake, October 18.

Granville L. Fox, M.D., to Miss Mamie McDade, both of Gallman, Miss., October 1.

Francis P. Patterson, M.D., to Miss Edith Adamson, both of Philadelphia, October 21.

William Cogswell, M.D., Boston, to Miss Miriam G. Clay oi Lexington, Ky., October 10.

Oliver Fisher, M.D., Sloan, Iowa, to Miss Nina Norwood of Denver, Colo., September 9.

Earnest R. Luckett, M.D., to Miss Nellie E. McDonald, both of Marengo, Ind., October 15.

Rose Fairbank, M.D., to Lester H. Beals, M.D., both of Ahnednagar, India, September.

Joseph K. Swindt, M.D., Pomona, Cal., to Miss Estelle Martin, at Denver, Colo., October 7.

Thomas Ford Huey, M.D., to Miss Mattie Marion Greene, both of Blocton, Ala., October 4.

Frank Wilbur Foxworthy, M.D., to Miss Leila Thomas, both of Indianapolis, October 11.

Earl Surrey Packwood, M.D., to Miss Ethel Lanore Jones, both of Buffalo, N. Y., October 4.

Thomas P. Bodkin, M.D., to Mrs. Julia Tanforan Pacheco, both of San Francisco, October 8.

Walter R. Evans, M.D., Jackson, Ohio, to Miss Anna Lewis of Columbus, Ohio, September 27.

Olen Roy Cooper, M.D., Banfield, Mich., to Miss Verna Davis of Battle Creek, Mich., October 3.

Harold Hargreave Roberts, M.D., Maywood, Ill., to Miss Leila Lines of Chicago, October 14.

Edward P. Crosby, M.D., Lomira, Wis., to Miss Edwina Burg of St. Anna, Wis., October 24.

John J. Catlin, M.D., Buffalo, Minn., to Miss Edith Anna Larkin of Alden, Minn., October 17.

M. Jean Wilson, M.D., Warsaw, N. Y., to Miss Charlotte Capwell of Dale, N. Y., October 12.

Herbert B. Williams, M.D., Gladys, Va., to Miss Sue Kabler of Campbell County, Va., October 3.

William D. Tucker, M.D., to Mrs, Isadore Ballou Flanders, both of Newburyport, Mass., June 14.

Irvine F. P. Turner, M.D., to Miss Olive Josephine Agnew, both of Titusville, N. J., October 25.

James R. Pharr, M.D., Dunloop, W. Va., to Miss M. Mattee Mulford of Richmond, Va., October 16.

Wilford W. Hawke, M.D., to Miss Aimee Josephine Pennypacker, both of Philadelphia, October 7.

Isaac Moore, M.D., Alton, Ill., to Miss Elizabeth Foree of Melville, Ill., at Quincy, Ill., October 5.

J. William Schultz, M.D., Tremont, Pa., to Miss Eva Viola Zimmerman of Sunbury, Pa., October 4.

James M. Fetterman, M.D., Hawthorn, Pa., to Miss Laura B. Ablett of Allegheny, Pa., October 4.

Beecher Franklin Stout, M.D., Kansas City, Mo., to Miss Liora Beach of Olathe, Kan., October 18.

Henry Rose Carter, M.D., to Miss Mary Washington Pendleton, both of Ashland, Va., October 18.

Earl Albert Mowry, M.D., Mexico, N. Y., to Margaret S. Brennan of Pompey, N. Y., September 27.

William Orlin Colburn, M.D., Stuart, Neb., to Miss Ethel Reighter of Kansas City, Mo., October 18.

Horace Rainsford Drew, M.D., to Miss Ethel Bluebell Conover, both of Jacksonville, Fla., October 4.

Harley Strohl, M.D., Waggoner, Ill., to Miss Grace Gill of Girard, at Springfield, Ill., September 28.

Fred Minty, M.D., Woonsocket, S. D., to Miss Mary Caroline Crawford of Sioux City, Iowa, October 10.

Henrik Tillisch, M.D., Canby, Minn., to Miss Maud Leanore Stokes of Watertown, S. D., October 4.

George Hughes, M.D., Mexico, to Miss Mary Caroline Babb of Philadelphia, at Chester, Pa., October 11.

Cortez Ferdinand Enloe, M.D., Jefferson City, Mo., to Miss Margaret Hammett of St. Louis, October 12.

Harry Gilmer Walcott, M.D., Dallas, Texas, to Miss Wayne Howeth of Gainesville, Texas, October 18.

James William Beasley, M.D., Daleville, Ala., to Miss Lula Virginia Dismukes of Union Springs, Ala., October 18.

Paul Kernan, M.D., Big Stone Gap, Va., to Miss Julia Graham Robinson of Graham's Forge, Va., October 12.

Harry Burton Roberts, M.D., Highland Park, Ill., to Miss Caroline Gertrude Brown of La Grange, Ind., October 17.

Frederick S. Burns, M.D., Boston, to Miss Josephine Lyman Boynton of Newport, R. I., at Middletown, R. I., October 3.

George Kittredge Butterfield, M.D., Taunton, Mass., to Miss Margaret Florence Fulton of Everett, Mass., October 3.

Deaths

Robert Henry Harrison, M.D. Cincinnati Medical College, 1846, a member of the American Medical Association, member and vice-president in 1875 and president in 1876 of the Texas State Medical Association; member of the American Association for the Advancement of Science, the South Texas Medical Association and the Colorado County Medical Association; consulting surgeon to, and late medical director of the Atlantic division of the Southern Pacific system; consulting surgeon to the G. H. & S. Ry., a distinguished line officer, inspector general and brigadier general in the Confederate service during the Civil War; an expert of national renown on yellow fever, and one of the best known and most beloved physicians of Texas, died at his home in Columbus, Texas, October 17, *from* paralysis, after a short illness, aged 78. Drs. William W. Cunningham, Beaumont; Robert W. Knox, Houston; Frank O. Norris, Eagle Lake; Matthew M. Smith, Austin; Walter Shropshire, Yoakum, and Samuel B. Mac Leary, Weimar, served as active pallbearers, and Drs. David F. Stuart, Houston; John N. Bowers, Columbus; Jaqulin S. Bruce, Eagle Lake; J. Hall Bell, San Antonio, as honorary pallbears at his funeral.

Louis A. Malone, M.D. Northwestern University Medical School, Chicago, 1885, of Indianapolis, a member of the American Medical Association and the Marion County Medical Society; who conducted a sanatorium for several years at Jacksonville, Ill., died at the Indianapolis City Hospital October 14 from cerebral hemorrhage, after an illness of two weeks, aged 47.

Asa Coleman, M.D. Jefferson Medical College, Philadelphia, 1854; for four years physician to the Indian Department in the territory of Minnesota, surgeon of the Forty-sixth Indiana Volunteer Infantry in the Civil War, a member of the Loyal Legion, was found dead in his office in Logansport, Ind., October 11, probably from heart disease, aged 72.

Joseph Huyett, M.D. Jefferson Medical College, Philadelphia, Pa., 1843, Illinois Army Board, 1862, one of the oldest practitioners in Illinois; surgeon of the Ninety-third Volunteer Infantry during the Civil War; councilman, assessor, collector and supervisor of Milan, Ill., died at his home in that city from senile debility, October 6, aged 85.

Wellington George Beyerle, M.D. Jefferson Medical College, Philadelphia, 1853, surgeon of the One Hundred and Forty-first Pennsylvania Volunteer Infantry in the Civil War, for many years treasurer of the Bernville (Pa.) school board, died suddenly at his home in that place, from cerebral hemorrhage, October 15, aged 74.

Abisha Shumway, M.D. Albany (N. Y.) Medical College, 1846, one of the organizers of the Keokuk (Iowa) Medical College, and a member of its faculty; surgeon of the Thirty-fourth Illinois Volunteer Infantry in the Civil War, died at his home in Mount Vernon, Ohio, from edema of the glottis, October 9, aged 86.

John O. McReynolds, M.D. Jefferson Medical College, Philadelphia, 1849, for many years a member of the Kentucky State Board of Health and health officer of Todd County; one of the oldest practitioners of western Kentucky, died at his home in Elkton October 6, after an illness of three weeks, from senile debility, aged 78.

George Walter McCallion, M.D. College of Physicians and Surgeons, Baltimore, 1896, city physician of Elizabeth, N. J., and a member of the Union County Medical Society, died in Alexian Brothers' Hospital in that city from acute uremia, September 29, after an illness of only a few hours, aged 33.

Charles L. Hart, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1865, hospital steward of the Sixteenth Connecticut Volunteer Infantry and afterward assistant surgeon, U. S. V., in the Civil War, died at his home in Longton, Kan., October 13, aged 62.

Albert M. Knapp, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1865, of Arlington, Providence, R. I., a member of the Rhode Island Medical Society, died at the Rhode Island Hospital, Providence, from uremia, after a short illness, October 10, aged 63.

John H. Dickenshied, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1847, said to have been the oldest practitioner in Lehigh County, Pa., died at his home in Plover October 17, from hemorrhage of the stomach, after a short illness, aged 80.

Alexander G. Lane, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1858, surgeon in the Confederate service and chief surgeon of Winder Hospital, Richmond, Va., during the Civil War, died at his home in Oakland, Cal., October 9, aged 70.

Norman K. MacKenzie, M.D. Medical College of Ohio, Cincinnati, 1844, a lifelong resident of Wellsville, Ohio, once postmaster of the city and at one time a member of the state legislature, died at the home of his son in Wellsville, October 13, aged 87.

Arthur Simonton Lynn, M.D. Hospital College of Medicine, Louisville, 1901, of Rock Hill, S. C., died at Rock Hill Hospital October 1 from tuberculosis of the intestines, for which he had had an operation in Baltimore, after an illness of two months, aged 29.

Lowell Holbrook, M.D. New York University, New York City, 1849, surgeon of the Eighteenth Connecticut Volunteer Infantry during the Civil War; in 1879 a member of the legislature, died at his home in Thompson, Conn., October 16, aged 87.

John B. Martin, Jr., M.D. Barnes Medical College, St. Louis, 1902, of Lohman, Mo., died at the City Hospital, St. Louis, October 8, from skull fracture from a blow received during the Veiled Prophet's parade, after an illness of five days, aged 26.

Frank M. Coates, M.D. University of Wooster Medical Department, Cleveland, 1871, professor of pharmacy in Baldwin University for two years, township health officer, died at his home in Berea, Ohio, October 7, after a long illness, aged 57.

Frederick Cole, M.D. Rush Medical College, Chicago, 1865, formerly of El Paso, Ill., surgeon of the One Hundred and Fifty-first Illinois Volunteer Infantry in the Civil War, died recently at his home in Garden City, Kan., aged 76.

Ulysses G. Hipp, M.D. Chicago, 1901, died at his home in Chicago, October 24, from the effects of an overdose of chloral, taken, it is supposed, with suicidal intent, aged 33. He had been despondent owing to continued ill-health.

August H. Holmgren, M.D. Royal University of Sweden, 1888, a member of the Mississippi Valley Medical Association, died at his apartments in Canton, S. D., October 17, from diabetes after an illness of more than a year.

William L. Godbold, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1867, surgeon in the Confederate service throughout the Civil War, died at his home in Knoxville, Miss., October 11, aged 73.

Vernon G. Culpepper, M.D. University of Virginia Medical Department, Charlotteville, 1876, died at his home in Portsmouth, Va., October 15, from cerebral hemorrhage, after an illness of a few hours, aged 52.

Asa Spalding Allen, M.D. Harvard University Medical School, Boston, 1830, of Cleveland, died at the home of his son in that city September 6, from senile debility, after an illness of one week, aged 94.

William Jay Gilbert, M.D. New York University, New York City, 1861, a practitioner of Wayne and Robeson counties, N. C., died at his home in Raeford September 9, from heart disease, aged 62.

Richard M. Kerley, M.D. Jefferson Medical College, Philadelphia, 1869, superintendent of the Female Hospital, St. Louis, from 1891 to 1895, died suddenly in his office in St. Louis October 19.

Franklin B. Kling, M.D. Baltimore Medical College, 1876, county physician of Dauphin County, Pa., a resident of Steelton, died suddenly at Williamstown, Pa., October 4 from heart disease.

James Earl Cox, M.D. Rush Medical College, Chicago, 1896, of Belleplaine, Iowa, died at Canon City, Colo., September 30, from tuberculosis, after an illness of nearly two years, aged 30.

Robert L. Harris, M.D. Tulane University of Louisiana, Medical Department, New Orleans, 1891, of Fulshear, Texas, died in New York City, October 11, after a long illness, aged 66.

Robert Winning Glassford, M.D. College of Physicians and Surgeons in the City of New York, 1878, of New York City, died in Roosevelt Hospital, New York City, October 18, aged 52.

James Glasgow Haywood, M.D. Memphis (Tenn.) Hospital Medical College, 1883, died at his home in Memphis, Tenn., October 4, from malarial fever, after a long illness, aged 43.

Giles Mebane McAden, M.D. Baltimore Medical College, of Charlotte, N. C., died in a hospital in New York City October 15 from pneumonia, after an illness of four days, aged 38.

Thomas M. Hinshaw, M.D. The Medical College of Indiana, Indianapolis, 1876, died at his home in Indianapolis, October 8, from cancer, after an illness of several months, aged 55.

Anna Cole Howland, M.D. New York, 1868, of Poughkeepsie, N. Y., died at Vassar Hospital in that city September 29, a few days after an operation for mastoiditis, aged 73.

Walter R. Benjamin, M.D. Bellevue Hospital Medical College, New York City, 1887, died at his home in Great Berrington, Mass., October 16, after a lingering illness, aged 42.

Henry William Koehler, M.D. University of Marburg, Germany, died at his home in Louisville, Ky., October 3, from pneumonia, after an illness of five days, aged 80.

Nelson H. Cornwell, M.D. Cincinnati, 1880, of North Amherst, Ohio, died in St. Alexis Hospital, Cleveland, September 21, after an operation for cholelithiasis, aged 58.

Jesse W. Connell, M.D. Bellevue Hospital Medical College, New York City, 1872, died at his home in New Liberty, Ky., October 14, from heart disease, aged 52.

Orletus Palmer Eaton, M.D. Detroit Medical College, 1872, of Detroit, died suddenly from heart disease at his farm at Bloomingdale, Mich., October 4, aged 60.

Lewis O. Ludlum, M.D. Geneva (N. Y.) Medical College, 1867, of West Branch, Mich., died at the home of his son in Ann Arbor, Mich., October 9, aged 70.

Edgar E. Martin, M.D. Memphis (Tenn.) Hospital Medical College, 1902, of Belcher, La., died at Roane, Texas, after a prolonged illness, October 6.

S. T. James, M.D. Atlanta (Ga.) College of Physicians and Surgeons, 1898, died at his home in Park Springs, Texas, from typhoid fever, October 14.

Matthew G. W. Jordan, M.D. Medical College of the State of South Carolina, Charleston, 1854, died recently at his home in Ruston, La., aged 80.

George H. Alexander, M.D. Detroit College of Medicine, 1894, was shot and killed by his son near his home in Hot Springs, Ark., October 9, aged 60.

Isaac H. Fry, M.D. Chicago Medical College, 1876, of Chicago, died suddenly in Arcata, Cal., from intestinal paralysis, October 4, aged 57.

Henry H. Boulter, M.D. Illinois, 1884, died at his home in Pensacola from yellow fever, October 3, after an illness of two days, aged 52.

Charles A. Gwynn, M.D. New York, 1888, committed suicide by stabbing himself in the heart, at his home in Auburn, N. Y., October 19.

Benjamin F. Greene, M.D. Cleveland, 1862, of Lynn, Mass., died at the home of his daughter in Peabody, Mass., September 18, aged 83.

J. William Clark, M.D. Medical College of Ohio, Cincinnati, 1870, died at his home in Gertrude, near Augusta, Ky., recently, aged 65.

E. Wendell Foster, M.D. The John A. Creighton Medical College, Omaha, Neb., 1902, died recently at his home in Cedar Creek, Neb.

Joseph W. Karten, M.D. Illinois, 1883, of Gervais, Ore., died at the Salem Hospital September 27, from septicemia due to a carbuncle.

Homer Bryan, M.D. Ohio, 1892, died from tuberculosis at his home in Beaver Falls, Pa., October 15, after a long illness, aged 48.

Ben H. Brodnax, M.D., died at his home in Brodnax, La., October 17, from typhoid fever, after an illness of six weeks, aged 73.

Franz Bacher, M.D. Heidelberg, Germany, 1848, died at his home in Quincy, Ill., October 15, from senile debility, aged 77.

Oscar E. B. Ewell, M.D. College of Physicians and Surgeons, Baltimore, died at his home in Marion, Md., October 6, aged 49.

Preston Bishop, M.D. Medical Department, University of Cincinnati, 1863, died at his home in Sligo, Ohio, October 15.

Edmund J. Howard, M.D. Rush Medical College, Chicago, 1888, of Corydon, Iowa, died at Saline, Ore., September 22.

Joseph W. Anderson, M.D. Jefferson Medical College, Philadelphia, 1862, died recently at his home in Ardmore, Pa.

Elizabeth Irwin, M.D. New York City, 1894, of New York City, died October 13, three weeks after an operation.

William H. Mansell, M.D. Atlanta (Ga.) Medical College, 1875, died at his home in Walthrall, Ga., October 1.

Bazil George, M.D. Medical College of Alabama, Mobile, 1872, died at his home in Enterprise, Miss., October 3.

Joseph W. Dostal, M.D. Rush Medical College, Chicago, 1892, died at his home in Chicago, October 4, aged 36.

Albert Arendt, M.D. Illinois, 1896, died at his home in Bloomington, Ill., October 22.

J. M. Gealy, M.D. Cincinnati, 1860, died recently at his home in Joseph, Ore., aged 72.

State Boards of Registration

COMING EXAMINATIONS.

Nebraska State Board of Health, State House, Lincoln, November 8-9. Secretary, George H. Brash, Beatrice.

Board of Registration in Medicine of Massachusetts, State House, Boston, November 14-15. Secretary, E. B. Harvey, Boston.

Connecticut Medical Examining Board, City Hall, New Haven, November 14-15. Secretary, Charles A. Tuttle, New Haven.

State Board of Health of Louisiana, New Orleans, November 14-15. Secretary, F. A. Larue, New Orleans.

State Board of Health of West Virginia, Clarksburg, November 14-16. Secretary, H. A. Barbee, Pt. Pleasant.

Illinois May Report.—In the report of the examination held at Chicago, May 3-5, 1905, published in The Journal, August 19, the general average attained by representatives of Rush Medical College was given as 88.3; this was an error, it should have been 87.4. The averages given for the other schools were as follows: Northwestern University, 87.6; American College of Medicine and Surgery, 81.4; Bennett Medical College, 82.2; College of Medicine and Surgery, 81.8; College of Physicians and Surgeons, Chicago, 84.2; Hahnemann Medical College, Chicago, 82.3; Illinois Medical College, 82.1; Jenner Medical College, 81.2; National Medical University, 79.

Oklahoma September Report.—Dr. J. W. Baker, secretary of the Territorial Board of Medical Examiners, reports the written examination held at Guthrie, Sept. 27, 1905. The number of subjects examined in was 10; total number of questions asked, 90; percentage required to pass, 66.6 in each branch. The total number of candidates examined was 22, of whom 17 passed and 5 failed. Representatives of the following colleges passed:

PASSED.

College.	Year. Grad.	Per Cent.
American College of Med. and Surg.	(1905)	88.4
University of Buffalo	(1902)	78.1
Med. Col. of Alabama	(1883)	74.1
University of Michigan, Homeo. Med. Coll.	(1905)	77.8
Kansas City Med. Coll.	(1905)	74.1
Northwestern University Med. Coll.	(1905)	77.1
College of P. and S., Dallas, Texas	(1905)	69.4
Eclectic Med. Inst., Cincinnati	(1890)	72.6
University of Vermont	(1899)	84.5
College of P. and S., Chicago	(1886) 67; (1905)	72.1
University Med. Coll., Kansas City, Mo.	(1905)	74.4, 78.2
University of Tennessee	(1903)	69.1
College of P. and S., Des Moines	(1896)	78.4
Hahnemann Med. Coll., Chicago	(1905)	76.1
Memphis Hospital Med. Coll.	(1904)	68.4

The following questions were asked:

OBSTETRICS AND GYNECOLOGY.

1. Define menstruation, vicarious menstruation, vitellus, allantois, amnion.
2. Give principal differences between the male and female pelvis.
3. Name the bones of the pelvis and define false and true pelvis.
4. Give the physical changes that occur during pregnancy.
5. Describe the human embryo at the second, fifth, seventh and ninth months, giving size and weight.
6. Define morning sickness, cause, appearance, duration and treatment.
7. Name the presentations liable to be met in labor; dispose of one abnormal one.
8. Define abortion, miscarriage, premature delivery, ectopic gestation, *caput succedaneum*.
9. Give your management of a case of confinement from the time your services are engaged until the case is discharged.

CHEMISTRY AND URINALYSIS.

1. Define element, atom, molecule, a salt.
2. In how many forms do we find matter in nature?
3. Define organic chemistry, inorganic chemistry.
4. What is the essential element of all acids?
5. Classify acids and name three of each class.
6. Explain the process of combustion.
7. Name the presentations liable to be met in labor; dispose of compounds used in medicine.
8. Five chemical antidote for bichlorid of mercury, carbolic acid.
9. Give common name of the following chemicals, $NaCl$, HNO_3, $MgSO_4$, KI, HgC_2, $AgNO_3$, H_2O, $2KClO_3$, CO_2, HCL.
10. Give in detail a reliable test for albumin in urine; for sugar in urine.

MATERIA MEDICA AND THERAPEUTICS.

1. Name three drugs belonging to each of the following classes: narcotics, stimulants, emmenagogues.
2. Mention the remedies you use hypodermatically and give indications for their use.
3. Give dosage of remedies you would use in typhoid fever and pneumonia.
4. Give dosage and indications for four remedies you use in rheumatism, [illegible], malarial fever.
5. Give Latin names, preparations, dosage and uses of twelve leading remedies you carry in your medicine case.

MEDICAL JURISPRUDENCE AND TOXICOLOGY.

1. What is malpractice?
2. What period of intrauterine life does the fetus become viable?

3. When is abortion legally justifiable?

4. How would you determine the presence of blood stains on clothing?

5. What mental condition renders a testator capable of making a will?

6. How would you treat a patient suffering from poisoning by coal gas?

7. What are symptoms and treatment for poisoning by the castor bean and what is considered a lethal dose?

8. What are symptoms of poisoning by wood alcohol and treatment for same?

9. What are symptoms and treatment for poisoning by muscarin or mushrooms?

10. Give symptoms and treatment for poisoning by turpentine taken internally.

PRACTICE OF MEDICINE.

1. Give treatment, medical, hygienic, and prophylactic of scarlet fever.

2. Give treatment and management of smallpox.

3. Give treatment of pertussis.

4. Give treatment, medicinal, hygienic, and prophylactic of typhoid fever, with treatment of most frequent complications that might arise.

5. Give treatment of a case of pneumonia.

6. Give treatment of a case of acute jaundice.

7. Give treatment, medical, hygienic and dietetic of acute gastritis.

8. Give treatment of a case of acute meningitis.

9. Give symptoms and treatment of case of follicular tonsillitis.

10. Give causes, symptoms and treatment of urticaria.

PHYSICAL DIAGNOSIS.

1. What is physical diagnosis and what are the methods employed?

2. Give cause, symptoms, pathology, diagnosis and prognosis of congestion of the lungs.

3. Give cause, pathology, symptoms, diagnosis and prognosis of acute pericarditis.

4. Give cause and symptoms of vertigo.

5. Give cause, symptoms, diagnosis and prognosis of renal calculi.

6. Give cause, pathology, symptoms, complications, diagnosis and prognosis of a case of acute Bright's disease.

7. Differential diagnosis between croupous and catarrhal pneumonia.

8. Differential diagnosis between erysipelas and scarlet fever in the early stages.

9. Give cause, pathology, symptoms, diagnosis and prognosis of

gnosis between varicella and variola (a) ; (b) period of eruption; (c) character of eruption.

PHYSIOLOGY.

1. Give the number of chemic elements in the human body.

2. Give the amount of saliva secreted in 24 hours in the adult, also give functions of saliva.

3. Give the amount of water and solids in the body of a person weighing 145 pounds.

4. Give the amount of blood (in pounds) in the body, and state the functions of the red corpuscles.

5. Give the amount of oxygen absorbed, carbonic acid exhaled and urine excreted in 24 hours.

6. Give, as far as known, the functions of the intestinal juices.

7. What are and where will you find the sebaceous and sudoriparqus glands?

8. What are the functions of the iris and retina?

9. Name the organs of digestion, in the order in which they belong.

10. Give the source of muscular energy.

ANATOMY.

1. Give the number and name of the bones in the trunk and of each upper extremity.

2. Name the articulations and muscles attached to the inferior turbinated bone.

3. What kind of a joint is the sternoclavicular articulation? Give the number of synovial membranes and ligaments around this joint.

4. What are muscles, how are they formed and what are their principal uses?

5. Give origin, insertion, uses and nerve supply of the flexor longus, pollicis, and the abductor pollicis.

6. Give the longest anastomosis in the body, also give the collateral circulation after ligature of the common carotid artery.

7. Give the number and names of the fissures of the cerebrum.

8. Name the branches and organs supplied by the inferior mesenteric plexus of nerves.

9 and 10. Locate and describe the uterus, vas deferens, Eustachian and Fallopian tubes, circle of Willis, Scarpa's triangle ureters and popliteal space, inguinal hernia and the entire colon.

SURGERY.

1. Give etiology, symptoms and treatment of inflammation, septic, traumatic, and surgical fever.

2. Define suppuration, abscess, ulcers, gangrene, septicemia, pyemia and anesthesia.

3. What do you mean by asepsis and antesepsis? Give a general outline to be followed by the surgeon, his assistants and attendants in preparing the room, instruments, etc., for some major operation.

4. Give symptoms and treatment of gonorrhea, orchitis, acute prostatitis, cystitis and stricture.

5. Give differential diagnosis between strangulated inguinal hernia, hydrocele, hematocele and varicocele.

6. How would you diagnose a case of hip dislocation upward on the dorsum of the ilium from a case of hip-joint disease?

7. Give the signs of fracture and state what you would call an infallible sign, also give the process of repair in fractures.

8. When does it become necessary to tap the bladder, and if necessary, where, and how would you tap?

9 and 10. Give differential diagnosis and a cure for hemorrhoids and prolapsus ani, housemaid's knee, subcellular synovitis, carbuncle and furuncle.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending October 21.

Keefer, Frank R., surgeon, Crosby, William D., surgeon, relieved from duty in n time to sail from Manila, Feb. 15, 1906,

Roberts, William, asst.-surgeon, ordered from Fort Hamilton, N. Y., to Fort Jay, N. Y., for temporary duty.

Gibson, Robert J., surgeon, relieved from duty at Fort Logan, Colo., to duty at Fort Adams, R. I.

Shaw, Henry A., surgeon, relieved from duty at Fort Adams, R. I., to duty at Fort Slocum, N. Y.

Morris, Edward order for duty at Fort Slocum, N. Y., revoked, to Fort y.

Krebs, Lloyd I relieved from duty in the Philippines Divisi Monterey, Cal., and ordered to duty at the Ar Fort Bayard, N. M.

Glennan, James D., surgeon, leave of absence extended for ten days.

Rand, Irving W., asst.-surgeon, leave of absence extended one month.

Dale, Frederick A., asst.-surgeon, leaves Lemont, Pa., October 15, at expiration of leave of absence, for his station, Fort Walla Walla, Wash.

Grubbs, Robert B., asst.-surgeon, leave of absence granted for one month, fourteen days.

Schreiner, Edward R., Dutcher, Basil H., asst.-surgeons, ordered to duty in the Philippines Division, and will sail from San Francisco, Cal., December 5.

Marrow, Charles E., asst.-surgeon, left attending surgeon's office, Chicago, Ill., October 17, for his proper station, Fort Sheridan, Ill.

Kennedy, James M., asst.-surg., left Washington, D. C., October 19, for proper station, Army General Hospital, Presidio of San Francisco, relinquishing remainder of leave of absence.

Hathaway, Levy M., asst.-surgeon, arrived at station, Fort Thomas, Ky., October 17, and left same day on leave of absence for two months.

Wilson, James S., asst.-surgeon, returned to duty at Fort Oglethorpe, Ga., from leave of absence.

Blanchard, Robert M., asst.-surgeon, left Fort Thomas, Ky., October 18, on leave of absence for ten days.

Juenemann, George F., left Fort Ringgold, Texas, on leave of absence for fifteen days.

Duval, Douglas F., asst.-surgeon, granted leave of absence for twenty days about October 25.

Holmes, Thomas G., contract surgeon, relieved from duty as examiner of recruits at Detroit.

Vall, Francis M., contract surgeon, granted leave of absence for fourteen days.

Waddell, Ralph W., dental surgeon, ordered from Fort Leavenworth, Kan., to Fort Crook, Neb., for one month.

Adair, George W., contract surgeon, leave of absence granted for fifteen days.

Tenney, Elmer S., contract surgeon, left Fort Strong, Mass., on leave of absence for ten days.

Sparrenberger, Frederick H., contract surgeon, returned to Fort Mott, N. J., from leave of absence.

Carpenter, Alden, dental surgeon, left Fort Liscum, Alaska, for Vancouver Barracks, Wash.

Shellenberger, James E., contract surgeon, arrived at Fort Sam Houston, Tex., from leave of absence.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending October 21.

Shaw, H., asst.-surgeon, detached from the naval recruiting rendezvous, Boston, and ordered to the Naval Hospital, Chelsea, Mass.

Dunbar, A. W., surgeon, ordered to the Naval Hospital, Mare Island, Cal.

Brister, J. M., P. A. surgeon, ordered to the Philadelphia, and to additional duty at the Navy Yard, Puget Sound, Wash.

Parker, E. G., P. A. surgeon, detached from the naval station, Tutuila, Samoa, and additional duty on the *Adams*, and ordered to the Pensacola, and to additional duty at the naval training station, San Francisco.

Fauntleroy, A. M., P. A. surgeon, detached from the *Philadelphia*, and from additional duty at the Navy Yard, Puget Sound, Wash., and ordered to the naval station, Tutuila, Samoa, and to additional duty on the *Adams*, sailing from San Francisco, November 2.

Elmore, B., asst.-surgeon, detached from the Naval Medical School, Washington, D. C., and ordered to the Naval Hospital, Washington, D. C.

Drake, N. H., medical inspector, detached from the navy yard, Norfolk, Va., and ordered home to wait orders.

Dickson, S. E. medical inspector, ordered to the navy yard, Norfolk, Va.

Bell, W. H., P. A. surgeon, detached from the *Dixie*, when placed out of commission, and ordered home to wait orders.

Porter, F. E., asst.-surgeon, detached from the *Dixie*, when placed out of commission, and ordered to the naval hospital, New York, N. Y.

Winn, C. K., acting asst.-surgeon, detached from the *Cæsar*, when placed out of commission, and ordered home to wait orders.

Guthrie, J. A., surgeon, ordered to the navy yard, League Island, Pa.

Brownell, C. DeW., surgeon, detached from the *Iowa* and ordered home to wait orders.

Morris, L., surgeon, detached from the *Florida* and ordered to the *Iowa*.

Elliott, M. S., surgeon, detached from the naval hospital, Norfolk, Va., and ordered to the Florida.

Gates, M. F., surgeon detached from the navy yard, League Island, Pa., and ordered to the *Charleston*.

Winn C. K., acting asst.-surgeon, orders of October 14, modified; ordered to the naval recruiting rendezvous, Omaha. October 23.

Oman, C. M., P. A. surgeon, commissioned P. A. surgeon, with rank of lieutenant, from Dec. 18, 1904.

Hoyt, R. E., P. A. surgeon, commissioned P. A. surgeon, with rank of lieutenant, from May 8, 1905.

Woods, E. L. asst.-surgeon, appointed asst.-surgeon, with rank of lieutenant (junior grade), from October 14, 1905.

Foster, T. G., asst.-surgeon, *detached from the naval hospital*, Norfolk, Va., and ordered to the Naval Medical School, Washington, D. C.

Elmore, B., asst.-surgeon, detached from the naval hospital, Washington, D. C., and ordered to the navy yard, Washington, D. C.

Hull, H. F., asst.-surgeon, detached from the Naval Academy and ordered to the naval hospital, New York, N. Y.

Baker, M. W., asst.-surgeon, ordered to the naval hospital, Washington, D. C., October 24.

Woods, E. L., asst.-surgeon, ordered to the Naval Medical School, Washington, D. C.

Rosenau, [illegible] directed to rejoin station in Washington.

Lumsden, L. L., P. A. surgeon, granted leave of absence for ten days, from October 20.

Glover, M. W., assistant surgeon, granted leave of absence for three days from October 15.

Hunt, Reid, chief Division of Pharmacology, hygienic laboratory, leave of absence for six days from October 9, revoked.

Hallett, E. B., acting asst.-surgeon, granted leave of absence for five days, from October 11.

Foild, Edward E., acting asst.-surgeon, granted leave of absence for one day, October 14.

Sinks, E. D., acting asst.-surgeon, granted leave of absence for five days, from October 6.

Sibree, H. C., acting asst.-surgeon, granted leave of absence for five days, from October 15.

Brown, F. L., pharmacist, granted leave of absence for sixteen days, from October 14.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service during the period from October 9 to 20:

SMALLPOX—UNITED STATES.

California: San Francisco, Sept. 23-Oct. 7, 9 cases.

Florida: Jacksonville, Oct. 7-14, 1 case.

Illinois: Danville, Aug. 8-Oct. 9, 1 case; Galesburg, Oct. 7-14, 3 cases.

Louisiana: New Orleans, Sept. 30-Oct. 14, 3 cases, 1 death.

Maine: Cooper, Oct. 6, present; East Machias and vicinity, present; Jacksonville, Sept. 27-Oct. 6, 5 cases; Wesley, Oct. 6, present.

Massachusetts: New Bedford, Oct. 7-14, 1 case.

Ohio: Cincinnati, Oct. 6-13, 1 case.

Pennsylvania: Altoona, Oct. 7-14, 2 cases, imported; York, 2 cases.

Washington: Tacoma, Sept. 23-Oct. 7, 2 cases.

SMALLPOX—FOREIGN.

Brazil: Pernambuco, Aug. 15-31, 283 cases, 283 deaths; Rio de Janeiro, Aug. 27-Sept. 30, 30 cases, 6 deaths.

Ecuador: Guayaquil, Sept. 20-27, 4 deaths.

France: Paris, Sept. 14-30, 22 cases, 4 deaths.

India: Calcutta, Sept. 2-9, 1 death; Madras, Aug. 16-Sept. 15, 1,553 deaths.

Italy: General, Sept. 14-28, 8 cases; Messina, Sept. 16-23, 1 death.

Russia: Moscow, Sept. 2-23, 13 cases, 3 deaths; Odessa, Sept. 16-23, 6 cases; St. Petersburg, Sept. 2-23, 11 cases, 2 deaths.

Turkey: Constantinople, Sept. 10-17, 1 death.

YELLOW FEVER—UNITED STATES.

Florida: Pensacola, Aug. 29-Oct. 8, 253 cases, 38 deaths.

Illinois: Chicago, Oct. 1-7, 1 death, imported.

Louisiana: Ascension Parish, to Oct. 7, 78 cases, 4 deaths; Assumption Parish, to Oct. 10, 40 cases, 1 death; Avoyelles Parish, to Oct. 7, 12 cases, 2 deaths; East Carroll Parish, to Oct. 10, 318 cases, 38 deaths; Iberville Parish, 33 cases, 8 deaths; Jefferson Parish, 4473 cases, 50 deaths; Lafourche Parish, to Oct. 6, 385 cases, 48 deaths; Madison Parish, to Oct. 9, 312 cases, 18 deaths; Natchitoches, to Oct. 9, 81 cases, 7 deaths; Orleans Parish, New Orleans, July 21-Oct. 11, 3,235 cases, 415 deaths; Rapides Parish, to Oct. 9, 24 cases, 1 death; St. Bernard Parish, 80 cases, 3 deaths; St. John the Baptist Parish, to Oct. 5, 177 cases, 18 deaths; St. Mary Parish, to Oct. 9, 801 cases, 31 deaths; St. Tammany Parish, to Oct. 10, 9 cases, 1 death; Terrebonne Parish, 311 cases, 13 deaths.

Mississippi: Gulfport, Aug. 15-Oct. 7, 107 cases, 2 deaths; Gulf Quarantine, July 22-Oct. 7, 68 cases, 1 death; Hamburg, Sept. 15-Oct. 7, 44 cases, 6 deaths; Handsboro, Sept. 17-Oct. 6, 5 cases; Mississippi City, Aug. 22-Oct. 6, 68 cases; Natchez, to Oct. 8, 93 cases, 5 deaths; Port Gibson, Sept. 27-Oct. 7, 44 cases, 1 death; Rosetta, to Oct. 8, 28 cases, 7 deaths; Soria, Sept. 14-Oct. 5, 2 cases; Vicksburg, Aug. 30-Oct. 8, 110 cases, 13 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Aug. 27-Sept. 20, 9 cases, 3 deaths.

Cuba: Sagua, Oct. 6, 1 case, on schooner.

Ecuador: Guayaquil, Sept. 20-27, 1 death.

French Guiana: Maroni River, to Sept. 15, 2 cases, reported.

Honduras: Cholera: Sept. 15-22, 1 case; Puerto Cortez, Sept. 19-26, 1 case; Rio Blanco, Sept. 15-22, 2 cases, 1 death; San Pedro, 2 cases.

Mexico: Coatzacoalcos, Sept. 23-Oct. 7, 5 cases; Soconusco, Oct. 7, 2 cases; Tezonapa, Sept. 17-30, 8 cases, 5 deaths; *Tierra Blanca*, Sept. 17-23, 1 case, 1 death; Vera Cruz, Sept. 17-30, 4 cases, 1 death.

Panama: Bocas del Toro, Oct. 1, 1 case; Panama, Sept. 20-27, 2 cases, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Manila, Aug. 23-Sept. 14, 172 cases, 150 deaths.

CHOLERA—FOREIGN.

China: Shanghai, to Sept. 13, 400 deaths.

India: *Bombay*, Sept. 12-19, 6 deaths; Calcutta, Aug. 26-Sept. 9, 62 cases; Madras, Aug. 26-Sept. 15, 969 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, Oct. 10, 1 case; Waipahu, Oct. 9, 2 cases, 2 deaths.

PLAGUE—FOREIGN.

Australia: Queensland, Townsville, Aug. 4, 1 case, 1 death.

Brazil: Rio de Janeiro, Aug. 26-Sept. 20, 41 cases, 14 deaths.

Egypt: Alexandria, Aug. 26-Sept. 2, 9 cases, 8 deaths; Assuan, 1 case; Damietta, 1 case.

India: General, Aug. 18-Sept. 2, 6,030 cases, 4,380 deaths; Bombay, Sept. 5-19, 75 cases; Calcutta, Aug. 26-Sept. 9, 26 cases; Karachi, Sept. 3-17, 48 cases, 48 deaths.

Peru: Callao, Aug. 21-Sept. 10, 2 cases, 2 deaths; Lima, Aug. 11-Sept. 10, 13 cases, 5 deaths; Mausiche, Aug. 11-20, 2 cases, 1 death; Mollendo, Aug. 21, Sept. 10, 2 cases, 1 death; Pampa Blanca, 1 case, 1 death; Payta, Aug. 11-Sept. 10, 28 cases, 13 deaths; Trujillo, Aug. 21-Sept. 10, 1 case, 1 death.

Zanzibar: Sept. 2, 6 cases.

Medical Organization

Georgia.

Hall County Medical Society.—This society was organized at Gainesville September 15 on the standard plan by Dr. W. B. Hardman, Commerce, state councilor for the ninth district, with an initial membership of sixteen. The following officers were elected: President, Dr. J. W. Bailey, Gainesville; vice-president, Dr. J. W. Oslin, Gainesville; secretary and treasurer, Dr. P. E. B. Robertson, Gainesville, and censors, *Drs. James H. Downey, New Holland; John B. Rudolph*, Gainesville, and William A. Palmour, Gainesville.

Muscogee County Medical Society.—Dr. W. L. Fitts, Carrollton, Ga., councilor for the fourth district, met the physicians of Muscogee County at Columbus August 26 and assisted in the organization of a medical society on the standard plan. Dr. Floyd W. McRae, Atlanta, and Dr. R. E. Lee *Barnum*, Richland, councilor for the third district, were also present. The following officers were elected: Dr. Charles L. Williams, *Columbus, president*; Dr. James H. McDuffie, Columbus, vice-president; Dr. Charles A. Dexter, Columbus, secretary; *Dr.* Thomas E. Mitchell, Columbus, *treasurer;* Drs. S. E. Young, Midland; John M. Crook, Columbus, and John I. Darby, Columbus, censors, and *Dr. William L. Bullard, Columbus,* delegate to the state association.

Stephens County Medical Society.—This society was organized on the standard plan at Toccoa September 18 with the aid *of Dr.* W. B. Hardman, Commerce, councilor for the *ninth* district, with nine charter members. The following officers were elected: Dr. Jeff Davis, Toccoa, president; Dr. W. L. *McBath*, vice-president; Dr. James H. Crawford, secretary and treasurer, and Drs. J. Claude Verner, John H. Edge, *Toccoa, and* W. H. Parker, censors.

Florida.

Lake County Medical Society.—This society was organized September 5 and the *following officers* elected: President, Dr. William P. McKee, Eustis; vice-president, Dr. T. Newton Lewis, Mt. Dora; secretary, Dr. Karl Mantey, Eustis; treasurer, Dr. Guy Hutchings, Eustis.

Illinois.

Chicago Medical Society, North Shore Branch.—This society has sent out an announcement of its program for the coming year. The circular is reproduced below, as *a* suggestion to county secretaries. This society is one of the district branches of *the* Chicago Medical Society.

Members of the North Shore Branch:

You are requested to assist the executive committee in preparing the program *for* the meetings this coming year *by* sending *to* the secretary *on* or before October 1, 1905, the subject of any papers you may wish to write or discuss, or have discussed. This subject to be *of* your own choosing *or* taken from some phase of the subjects as outlined below. As soon as these suggestions are received from the members the committee will arrange the program. This program does not prohibit *the presentation of other* papers and discussions which members may request during the year. Kindly insert title of paper, your name and address opposite subjects indicated below, or in blank space at bottom.

R. E. Green, Secretary.

OUTLINE OF PROGRAM.

Oct. 3, 1905.—Informal discussion: "Business Side of Physician's Life."
Nov. 8, 1905.—"Early Diagnosis of Smallpox."
Dec. 5, 1905.—"Tuberculosis."
Jan. 2, 1906.—"The Relation of Mental Disorders to General Medicine."
Feb. 6, 1906.—"Insects as Disease Carriers."
March 6, 1906.—"Infant Feeding."
April 3, 1906.—"Annual Reception and Banquet."
May 1, 1906.—"Skin Diseases as Seen by the General Practitioner."
June 5, 1906.—"Intestinal Obstruction."

I will present a paper on the following subject at the.......... meeting: ....I desire the following subject discussed: ....

Minnesota.

Aitkin County Medical Society.—Physicians of Aitkin County met at the office of Dr. J. Fowler Avery, Aitkin, September 19, to attempt to revive the organization. The following temporary officers were elected to serve until October 5, when the organization is to be completed and constitution and by-laws adopted: Dr. Carlton Graves, president, and Dr. A. G. Belsheim, secretary, both of Aitkin.

Fifth Councilor District Medical Society.—A joint meeting of the societies in this district, comprising the societies of Renville, Chippewa, Lac qui Parle, Lyon-Lincoln, Yellow Medicine-Sibley and Brown-Redwood Counties, was held at Redwood Falls September 12. Dr. Henry M. Workman of Tracy, councilor for the district, presided. Dr. J. N. McCormack of Bowling Green, Ky., and Dr. Charles H. Mayo of Rochester, president of the Minnesota State Medical Association, were present and addressed the meeting.

Sixth and Eighth District Medical Society.—A meeting of the physicians of Southern Minnesota from the counties making up the sixth and eighth councilor districts, was held at Mankato September 13, when Dr. J. N. McCormack, national organizer of the American Medical Association, delivered an address on "The Advantages of Organization." The physicians of Mankato entertained those who attended the meeting at a lunch. Dr. Adolph O. Bjelland, Mankato, councilor of the eighth district, presided.

Ninth District Medical Society.—The societies making up the ninth councilor district met at Fergus Falls September 9 and perfected a district organization, Dr. Eugene A. Hensel, Alexandria, being chosen secretary. Dr. J. N. McCormack, national organizer of the American Medical Association delivered an address in which he discussed the value of organization as the means of professional advancement, holding that conventions and the discussion of scientific topics assist materially in keeping physicians informed in regard to the latest discoveries in medical and surgical science. He also urged the advantages of organization in protecting the profession from quacks and irregular practitioners.

Montana.

Silver Bow County Medical Association.—Dr. J. N. McCormack, national organizer of the American Medical Association, gave an address before a large gathering of physicians of Butte, under the auspices of the Silver Bow Medical Association September 24, in which he set forth the advantages of organization.

Yellowstone Valley Medical Association.—The physicians of Eastern Montana met in Billings September 20 and organized this society on the standard plan. Dr. Donald Campbell, Butte, president of the State Medical Association, presided. [illegible] were elected: President, Dr. Henry E. [illegible] vice-president, Dr. Joseph H. Rinehart, [illegible] Charles F. Watkins, Billings; treasurer, Dr. Carl Schulin, Billings, and trustees, Dr. Henry E. Armstrong, Billings; Thomas D. Tuttle, Helena; W. L. Seamon, John L. Weitman, Great Falls, and James Chapple, Billings.

South Carolina.

Orangeburg County Medical Society.—A meeting of the physicians of the county was held in Orangeburg September 4, at which Dr. Theodore G. Croft, Aitken, councilor for the second district, was present. The society was organized on the standard plan and a constitution and by-laws adopted. The following officers were elected: President, Dr. W. L. Pou, St. Matthews; vice-presidents, Drs. Manley, J. D. Dantzler, Elloree, and Marion S. Grissett, Branchville; secretary and treasurer, Dr. Linn C. Schut, Orangeburg, and censors, Drs. A. R. Able, St. Matthews; Arthur W. Browning, Elloree, and Michael G. Salley, Orangeburg.

Society Proceedings

COMING MEETINGS.

American Academy of Medicine, Chicago, November 9-10.
Southern Surgical and Gynecological Association, Louisville, Ky., Dec. 12-14.
American Dermatological Association, New York, Dec. 28-30.
Western Surgical and Gynecological Association, Kansas Mo., Dec. 27-28.

SECOND INTERNATIONAL SANITARY CONVENTION.

Held at Washington, D. C., Oct. 9-14, 1905.

The President, Dr. Walter Wyman, in the Chair.

The Second International Sanitary Convention was called to order by the president, Dr. Walter Wyman, Surgeon-General, U. S. Public Health and Marine-Hospital Service, at 10 a. m., October 9. Addresses were made by Secretary of State Root, the Assistant Secretary of the Treasury Taylor, Hon. W. C. Fox, director of the International Bureau of the American Republics, Minister Quesada of Cuba, and the president, Dr. Walter Wyman.

Delegates.

The following delegates were present:

Senor Dr. Don Eduardo Moore, of Chile.
Senor Dr. Don Juan J. Ulloa, of Costa Rica.
Senor Dr. Don Juan Guiteras, of Cuba.
Senor Dr. Don Enrique B. Barnet, of Cuba.
Senor Dr. Don Serafin S. Wither, of Ecuador.
Senor Don Miguel H. Alcivar, of Ecuador.
Senor Dr. Don Joaquin Yela, of Guatemala.
Senor Dr. Don Eduardo Licéaga, of Mexico.
Senor Dr. Don J. L. Medina, of Nicaragua.
Senor Dr. Don Daniel Eduardo Lavoreria, of Peru.
Senor Don Pedro R. Bermudez, of Uruguay.
Senor Don Emilio C. Joubert, of the Dominican Republic.
Senor Don Nicolas Veloz-Goiticoa, of Venezuela.
[illegible]lter Wyman.
[illegible] U. S. Pub. H. and M. Hosp. Serv.
Dr. J. F. Kennedy, Iowa.
Dr. John S. Fulton, Maryland.
Dr. Walter D. McCaw, U. S. A.
Dr. J. F. Gatewood, U. S. N.
Dr. H. L. E. Johnson, Washington, D. C.

The following physicians were granted the privilege of the floor: Medical Director John C. Wise, U. S. N.; Drs. L. O. Howard, Preston H. Bailhache and Reid Hunt, of the Public Health and Marine-Hospital Service; the president of the Navy Medical School; the president of the Army Medical School; the surgeon-general of the United States Navy; the surgeon-general of the United States Army; Surgeon-General George M. Sternberg, retired; Dr. Wardell Stiles; the health officer of the District of Columbia; Dr. H. C. Wood, Philadelphia; Surgeon-General S. Suzuki, of the imperial Japanese Navy, and Dr. James Carroll, U. S. Army.

Elections and Reports.

After the appointment of an executive committee and the re-election of Surgeon-General Walter Wyman as president and the election of Dr. J. J. Ulloa as permanent secretary, the delegates to the convention were taken to the National Filtration plant, which is in the course of construction in the District of Columbia.

The following day, October 10, the delegates were taken on a government ship to Mount Vernon and Indian Head, the United States proving station. In the evening they were entertained at the Corcoran Gallery of Arts.

The executive committee presented the name of Dr. Eduardo Licéaga, who was elected president of the third convention, which is to meet in Mexico City in 1907, with Dr. Ulloa as secretary. Then followed an interesting address read by Dr. Licéaga in Spanish, accompanied by the English translation in pamphlet form which was distributed among the delegates. Addresses were made by Drs. Moore, Wither, Guiteras and Ulloa. President Wyman called for the reports of the delegates representing the several countries, which were read and referred to the executive committee for report.

Reception by President Roosevelt.

October 12, President Wyman announced that the delegates would be received by the President of the United States at the White House, saying:

"*Gentlemen:* We are about to proceed to the White House to pay our respects to President Roosevelt. Before starting I wish to assure you that you will have a cordial reception and that you will, without doubt, be greeted with words of encouragement as regards the objective aims of this convention. I wish to state that no other president of the United States has publicly expressed so often and so eloquently an appreciation of the character and labors of the physician in regard to his sacred relation to his patients, to his civic duties, and to his labors as a sanitarian.

"In his address before the Association of Military Surgeons of the United States, his [illegible] nt in Washington erected to [illegible] the laying of the corner s[illegible] very recently before the As[illegible] his words were words of [illegible] declared that in military life the surgeon, besides being a surgeon, bears all the hardships of a soldier and the responsibilities of an administrator; he has declared that the physician who stands high in his profession in any city counts as one of the most valuable assets in that city's civic work, that 'no doctor can be a good doctor or a good citizen unless he does his duty by the state, and that doctors must personally pay attention to their civic duties because "everybody's business is nobody's business." It must not be left to everybody, but individually the medical man should take an interest in state matters.'

"He has thus shown his appreciation of the sentiments that are so dear to us as physicians and sanitarians, namely, that our labors are highly essential to the welfare of the state as well as to the individual. In exemplification of this he has expressed the greatest interest and confidence in the work of the sanitarians of the Isthmian Canal Zone, and has taken an initiative, the good results of which are incalculable in the sanitary work which was begun and is still being conducted in New Orleans against the yellow fever pestilence.

"In expressing this appreciation of our president I am only echoing the voluntary expressions which I have heard on many sides, and particularly at the recent session of the great American Medical Association in Portland, Oregon, where comments of the above nature were frequent, prompted solely by appreciation in the minds of the medical profession of the sentiments and support of our president in matters relating to individual and public health."

The President received the delegates, greeting them most cordially, and showed great interest in the purpose of the convention. He made the following address, requesting Dr. Ulloa to interpret his remarks into Spanish for him:

President Roosevelt's Address.

Dr. Wyman and Gentlemen and Ladies of the Convention: I should like to greet you and say with what peculiar pleasure I welcome you, because both of the profession you represent and of the fact that you come from our sister republics of America.

I believe that we on this hemisphere are going to show to all the world—are going to teach all the world by an object lesson—that separate states, separate nations, can dwell together in absolute harmony and can unite in a common effort, as you are uniting here, for the betterment of the conditions affecting them all.

The outside world is only beginning to understand the astonishing progress made, not only socially and industrially, but in science, literature and art, by the Central and South American republics. In medical matters, in industrial, scientific, social, artistic matters, each of our countries has something to learn from the others; and I welcome you as colleagues and as teachers.

Of course, I could not overstate the all-importance of the medical profession in modern life and, as it is now becoming, in modern international life. In the old days a plague that happened in one country was regarded as only concerning that country until it spread over into some other helpless to defend itself against it. Now we recognize that the stamping out of disease, the warfare against unhygienic conditions, must be done by the organized effort of the medical profession of all the countries joined together.

Pharmacopeia in Spanish.

At the afternoon session of October 12 Dr. Guiteras presented the following resolutions concerning the U. S. Pharmacopeia. They were unanimously adopted:

Whereas, The decennial edition of the United States Pharmacopeia has just been published and issued by the board of trustees of the United States Pharmacopeial Convention.*

Whereas, This revised Pharmacopeia embraces many new forms of value for use both in therapeusis and in prevention of epidemic disease, and represents the best thought and labor of experts on these matters; therefore, be it

Resolved, That a translation of this United States Pharmacopeia into the Spanish language would prove of great benefit to the medical profession [illegible] h of the republics represented in this [illegible]

Resolved. Th[illegible] be referred to the several governments to report on at the next meeting in Mexico, with a view to the adoption of an international pharmacopeia for the American republics.

Etiologic Naming of Disease.

Dr. H. C. Wood addressed the convention, taking for his subject "The United States Pharmacopeia." Dr. L. O. Howard made an address on the "Geographic Distribution of the Yellow Fever Mosquito." Dr. H. L. E. Johnson read the following paper, entitled "Will Etiologic Naming of Diseases Influence Public Opinion?"

Mr. President, Members of the Conference and Guests: The principal object of sanitary and medical science and study at the present time is the prevention and limitation of disease. Pathologic, biologic and chemical laboratory investigations have made valuable advan[illegible] cause and origin, transmission, scientific [illegible] and arrest of many of the morbid processes affecting mankind and the lower animals.

Much good has been accomplished, more good will follow as a result of future labors, but before a universal acceptation and a successful *practical application of the facts demonstrated in the laboratory* is possible it is apparent that the lay public must be instructed and convinced.

The lay public is generally skeptical about new medical facts and discoveries, and until they appreciate the value and importance of sanitary, curative and preventive measures they will ridicule our teachings and obstruct our methods.

Legislators keep pace with the lay public and press; consequently sufficient appropriations for maintaining proper health conditions are seldom made either by a state or nation.

Generally speaking, belief on the part of the public in our theories of cause and prevention of disease is essential in our crusades for health, and to this end health matters should be made part of even a common school education and should be supplemented by systematic public lectures in terms appreciable by all. The baths gave Rome her health and vigor.

The relation of fly infection as a factor in enteric fever and tuberculosis is established, also the rôle played by the mosquito in malaria and yellow fever, but the lay public and press, notwithstanding the unanimity of medical opinion on these points, has not entirely indorsed our views or given us necessary support in our efforts to overcom[illegible] eases.

Cause and effect in c[illegible] early demonstrated to the public, and those [illegible] for their dissemination on an intermediary host, as, for example, malaria and yellow fever, should be given a name associated with or indicating their etiology, viz.: Malarial fever should be called anopheles fever, infection or poisoning; yellow fever, stegomyia fever, infection or poisoning. Thus named, their origin would be indicated and the necessity for the extermination of the insects which cause the respective diseases forcibly suggested. The medical profession and the public are mutually dependent for the promotion of sanitation and elimination of disease, and co-operation in these matters depends largely on a liberal education of the public along the established health lines.

The following delegates were elected as vice-presidents of the congress: Dr. Eduardo Moore, of Chile; Dr. Juan J. Ulloa, of Costa Rica; Dr. Juan Guiteras, of Cuba; Dr. Miguel Alcivar, of Ecuador; Dr. Joaquin Yela, of Guatemala; Dr. Eduardo Licéaga, of Mexico; Dr. L. Medina, of Nicaragua; Senor Emilio Joubert, of Santo Domingo; Dr. H. L. E. Johnson, of the United States; Dr. Eduardo Lavoreria, of Peru; Senor Bermudez, of Uruguay; Senor Veloz-Goiticoa, of Venezuela.

The convention also elected Drs. Wyman, Moore, Licéaga, Ulloa, Guiteras, Rhett, Goode, of Mobile, Ala., and A. H. Doty, of New York, members of the International Sanitary Bureau for a period of three years. This bureau will be clothed with semi-executive and judicial powers by the several governments and will decide on all questions relative to international sanitary arrangements.

October 13 and 14 were entirely devoted to the consideration and adoption of the sanitary agreements (which will appear next week).

NEW YORK STATE MEDICAL ASSOCIATION.

Annual Meeting, held at New York City, Oct. 16-19, 1905.

(Continued from page 1257.)

Amalgamation Approved.

Further details of the action taken by the New York State Medical Association at its annual meeting, on October 17, to which we referred editorially last week (page 1253), are as follows:

Resolutions were presented authorizing a committee to carry out the consolidation, and Dr. W. R. Townsend moved that the resolutions be adopted. They are as follows:

Resolved, That the New York State M[illegible] eby approves and adopts the agreement of [illegible] by the joint committee of conference appoint[illegible] tate Medical Association and the Medical Soc[illegible] New York, dated Jan. 23, 1904, and heretofo[illegible] ular and a special meeting of the Medical So[illegible] New York in the year 1905, a copy of which is hereto annexed. And be it further

Resolved, That a committee, consisting of E. Eliot Harris, Julius C. Bierwirth, Alexander Lambert, Parker Syms and Wisner R. Townsend, is hereby appointed, or, in case of the disability of any of them, then of such other persons as the president may appoint in his or their place and stead, to carry out the purposes of said agreement and with full and absolute power to take any and all legal steps necessary in the premises, in the place of the said the New York State Medical Association, as may be necessary, to complete the consolidation of the New York State Medical Association and the Medical Society of the State of New York.

Dr. E. Eliot Harris seconded the motion and said that he believed the agreement between the Medical Society of the State of New York and the New York State Medical Association was fair, just and equitable. The plan of reorganization of the consolidated state body is the plan of organization of the New York State Medical Association. The essential features of that plan are, first, that every member of the county medical society shall be *ipso facto* a member of the state society, and every member of the state society shall be a member of the county society; second, the constituent county societies shall elect annually the members of the house of delegates, which shall transact all the business of the consolidated society; third, there shall be a constitutional provision for a referendum on all questions referred by, or taken from, the house of delegates, and the vote of a majority of the whole association shall be binding on the house of delegates, the general meeting, and every member of the society. The permanent members of the Medical Society of the State of New York and the privilege they enjoyed of continuing as such members after they arrived at the age of 60 without the payment of dues have been excluded from the agreement and they are now compelled to go back and seek membership in their societies in order to be members of the consolidated body.

---

*Verbiage slightly corrected, because of error in name, not discovered till resolutions had been passed.

All the rights, powers and privileges of the New York State Medical Association are to be enjoyed by the consolidated society, and all the obligations and liabilities of the New York State Medical Association shall be assumed by the consolidated Medical Society of the State of New York. The agreement protects the rights of members of the New York State Medical Association by making the length of time of membership in the association count as equal time of membership in the society in determining the eligibility for office. The dues will be assessed pro rata from the date to which they are paid in the association, and all members of the association will be specially notified of the date set for the reorganization of the county societies so as to make their by-laws agree with the constitution and by-laws officially known as Exhibit B of the agreement. The journal and directory are not part of the agreement, as they do not belong there, but should be considered in the house of delegates of the consolidated body. They do not appear in the by-laws of the New York State Medical Association, although we have had a special committee on by-laws for several years past.

The ethical question is cared for by the referendum, which is ordered by the court in Section 7 of the agreement. It is to be fairly and squarely decided by a majority mail vote of the full membership of the consolidated body, which is good American doctrine.

It now remains for this association to be true to itself and to carry out the broad principles embodied in the agreement by recording its vote in favor of the resolutions now before you in the interest of the medical profession of this state and, through this state, of the United States.

Dr. Edwards, of Syracuse, moved to strike out the referendum part of the agreement, but later withdrew his motion.

Dr. Kaufman, of Onandaga County, said that last year he opposed the amalgamation in the courts, but he came to the meeting this year with all the proxies from his county in favor of the agreement to consolidate the two state bodies.

Dr. Joseph D. Bryant stated that, as president of the Medical Society of the State of New York, he sent out 6,100 copies of the Principles of Medical Ethics to the members of the society, who would now be ready to vote intelligently on the question of their adoption as provided in the agreement.

Dr. James G. Orten, of Binghamton, a former president of the association, said he would be glad to be enrolled as a member of the consolidated society.

The roll of membership was called and in proper legal form the vote was recorded on the question of the adoption of the resolutions, which included the agreement and the new constitution and by-laws. There were 1,814 members whose dues were paid and who, therefore, had a right to vote. Each one had been legally notified of the proposed meeting and the action to be considered; 1,517 voted aye, or in favor of the resolutions either personally or by proxy; 295 did not vote; 2 voted against the adoption of the resolutions.

Thus every known legal requirement was observed in notifying members of the annual meeting and in recording their vote on amalgamation.

(To be continued.)

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Annual Meeting, held in Scranton, Sept. 26-28, 1905.

(Continued from page 1272.)

Teaching the Deaf Child to Hear.

Dr. G. Hudson-Makuen, Philadelphia, referred to cases reported in the beginning of the last century by Itard and Toynbee of marked improvement in the hearing of deaf persons as a result of so-called aural gymnastics. Urbantschitsch found the use of musical instruments to be of value in diagnosis, and in one of Dr. Makuen's cases the piano furnished the only sound to which any response was given. The exercises were commenced with sounds similar to those of which the patient showed some appreciation, when the sounds of the human voice were gradually taken up. Dr. Makuen enumerated the following conclusions of his observation and treatment: 1. The hearing of the deaf child may be greatly improved by the systematic use of aural gymnastics; 2, the speaking voice used in close proximation to the ear is the most effective form of aural gymnastics for children; 3, the training of speech should be carried on simultaneously with the hearing exercises; 4, the degree of success attained will depend largely on the patience and skill of the teacher.

Address in Hygiene and State Medicine.

Dr. G. W. Wagoner, Johnstown, said that sanitary work, to be effective, must have back of it an authority, either assumed or delegated. The people must believe that it is necessary and have faith in the competency of those who undertake the work. The great value of sanitary knowledge is well illustrated in the work of the State Board of Health following the Johnstown flood. He reviewed the law "creating a Department of Health, and defining its powers and duties," recently passed by the Pennsylvania legislature. If the law is executed in an impartial, kindly and wise manner, it will deserve the cordial support of all, but if its opportunities for tyranny are taken advantage of the public will compel its repeal. It is the physician's duty to stand between the rigors of the law and the public as an advisor, a mediator and as an instructor of the people that they may accept the results of its enforcement.

Protective Inoculations Against Typhoid Fever.

Dr. D. H. Bergey, Philadelphia, said that the value of protective inoculations could only be determined by carefully following out the health of inoculated as compared with the health of uninoculated persons living under the same conditions. It was observed that the reduction in the incidence of typhoid fever among those inoculated by the Wright method varied greatly in different troops, also in regard to the number of injections made. In some instances the incidence was reduced one-half, while in others there was a reduction varying from a sixfold to a twenty-eight-fold reduction. The case mortality among the inoculated as compared with the uninoculated was reduced more than 50 per cent. While the method was considered of value by Dr. Bergey, he maintained that there should be no less energy used in eradicating all known sources of infection by the well-established means known to sanitarians.

Pain of Obscure Origin Simulating Neuritis, Neuralgia or Organic Lesions.

Dr. John H. Musser described illustrative cases and said that in the elucidation of such cases a thorough study should be made of the nerve itself, of the spinal cord, of the sensory and motor phenomena and of the reflexes of all kinds. In connection with a consideration of possible lesions along the course of the nerve trunk the anatomic conditions must be recognized; bony, vascular and muscular lesions must be considered before a definite diagnosis is made. The general phenomena attendant on the case should be studied and too much reliance should not be placed on sedative drugs. Dr. Musser is so thoroughly convinced of the frequent surgical source of pain that, generally speaking, he would rather resort to the knife, even though he sometimes did it wrongly, than to the hypodermic needle.

Case of Malignant Lymphoma with Autopsy.

Dr. J. A. Lichty, Pittsburg, reported the case of a patient aged 67 who had been sick two years. There was primary enlargement of the spleen, absence of leucocytosis, gradual decrease of leucocytes, anemia, comparatively large number of erythrocytes; presence of pigmentation and of subcutaneous hemorrhage; absence of enlargement of lymph glands; no history of malaria, leukemia, syphilis or cirrhosis of the liver. In the course of the disease there occurred enlargement of the liver and ascites. A diagnosis of splenic anemia was made. At autopsy there was found a great infiltration of lymphoid cells in the liver and the spleen, and the lymph glands about the coeliac axis were enlarged. He concluded that the diagnosis of splenic anemia should be made with great reservation, and that it is more than likely that at present it is made too often.

Chronic Rheumatism.

Dr. Charles W. Painter, Boston, stated that his classification of chronic rheumatism is based on the etiology, the clinical course and phenomena and the pathology of the disease. He divides chronic rheumatism into three groups. In the first group, which seems to be associated with some infective organism, the joint manifestations are acute in character, more or less rapid in their development, and are accompanied by constitutional symptoms characteristic of an infection. The second group, the atrophic, is not inflammatory either on onset or progress, and seems to be associated with some metabolism of the body. This disease is more common in women and in young adult life and is associated often with nervous shocks. In this group lesions are found in the cartilage and bone as well as in the soft parts, thus differing from lesions in the infectious type. In the third group, the hypertrophic, he placed Heberden's nodes, morbus coxae senilis, and similar lesions occurring in the spine, the knee, the elbow, etc., the lesions being characterized by a hypertrophy of cartilage about the joint lines and subsequently a true bone formation which is permanent and gives rise to mechanical disturbance more than to any constitutional disability. Dr. Painter commended his classification as a useful working hypothesis, one which would do away with the necessity for indiscriminately prescribing the salicylates for the interior and the oil of wintergreen for the exterior, and the statement that the condition was chronic rheumatism for which nothing could be done.

Dr. James J. Walsh, New York City, emphasized the necessity for individualization, and to recognize the fact that under the group of chronic rheumatism there were a number of diseases which could be benefited by medicine only when separated. Referring to occupation neuroses he asserted that there was not a single occupation in which a person performed a habitual motion which would not cause pain around the joints thus associated. A change in the barometer, he said, would cause pain in a tooth, if it happened to be bad, a pain in the arm, if it were overworked, and such pain is not greatly different from that which is called rheumatism.

Dr. DeForest Willard thought it the bane of the medical profession that pains were called rheumatism without making any diagnosis relative to the cause of the symptoms. He has seen cases which had been allowed to go to bone destruction and were still treated for rheumatism.

Diagnostic Value of Blood Cultures.

Dr. David L. Edsall, Philadelphia, said that in cases of bacterial infection in which the bacteria get freely into the blood the cultures have been of much value. A case of mastoid disease was cited in which it was not thought by the ear specialist that there was sufficient evidence of mastoid disease, but a positive culture of colon-like bacillus was found. In a series of gynecologic and obstetric cases, in which the local source of infection could not be found, blood cultures revealed an abscess in the wall of the uterus.

Some Color Comparisons in Medicine.

Dr. Henry E. Wetherill, Philadelphia, called attention to an improved hemoglobin scale called the ante-mortem blood color scale. The advantage claimed for it was that it gave the true percentage of hemoglobin. Another scale determined the weight of the perspiration; another the color of the feces. Other scales were for the determination of the color of postmortem blood and of the urine. Another scale was an improvement on Bell's scale for testing the amount of hydrochloric acid in the gastric filtrate.

Address in Neurology.

Dr. E. E. Mayer, Pittsburg, discussed the limitations of psychology and biology to explain clinical psychiatry. A plea was made for physicians to recognize mental diseases as a part of general medicine and to study them. He considered neurasthenia as always being a psychasthenia and hypochondriasis as being only a symptom of psychasthenia.

Insanity in the Aged.

Dr. Charles W. Burr, Philadelphia, spoke of the difficulty of determining the mental condition of the aged, because there is no dividing line between normal and pathologic senility. The best rule to follow is to discover whether the man knows what he wishes to do, whether he is competent to recognize the duty he owes toward his relatives, and is not swayed by momentary passion or delusions. He also spoke of the frequency of acute insanity in old age (mania and melancholia), and stated that the outlook as to cure was almost as good as in younger people. While it is true that physical and mental old age run along together, yet the saying that "a man is as old as his arteries," Dr. Burr believes is not true in every case. He said that there are a certain number of people who become prematurely senile while the physical organism remains in fairly good condition. In the consideration of postparalytic insanity, he thought that it is perfectly possible for an old man, after an ordinary hemiplegia, to remain in fit mental condition to take care of himself, but if there was also sensory aphasia or an extreme diffuse arterial disease there would surely be more or less dementia. Occasionally apoplexies in old people are ushered in with a period of excitement.

Brain Abscess with Sudden Exophthalmos and Blindness.

The condition in Dr. Heckel's case developed suddenly in a married woman, 22 years of age, whose previous history had been negative, except that suspecting herself to be pregnant, she had been persuaded to take some patent preparation with the object of producing an abortion. The condition which attracted most attention was the sudden exophthalmos and blindness, which was complete within a few hours. Curettage showed no signs of pregnancy. A typical septic temperature zigzagged between 105 and 99. In addition to the exophthalmos, hemorrhages appeared in both anterior chambers. Death occurred eight days after the appearance of the exophthalmos. The patient did not complain of headache until the day previous to death. Streptococci were found, but no abscess formation in any part of the body. In the left frontal lobe there was a cavity about the size of a hen's egg apparently filled with purulent fluid, but which was demonstrated to be a clot. There was no limiting membrane, but the cavity was studded with small millet seed granulations so that even after the thorough autopsy a positive diagnosis was doubtful.

Clinical Examination of the Feces.

Dr. J. Dutton Steele, Philadelphia, employed the method of Adolph Schmidt in these examinations, with a few modifications. He said that this so-called functional examination of the stools, has its limitations when used as a method of diagnosis, but is of great value in following the digestibility of various food-stuffs in determining the proper diet in any given case. The method is simple and easy to carry out, and bids fair to be an accurate means of watching the power of the gastrointestinal tract to digest certain food; hence would be of great use therapeutically and, in a general way, of considerable value in diagnosis.

Diaphragmatic Hernia with Complete Extrusion of Stomach and Spleen.

Dr. J. Bruce McCreary, Shippensburg, detailed the history of the case, that of a man of 22, who fell in collapse after having run a footrace. His usual health was not recovered until the end of two years, when he still, however, experienced a feeling of pressure in the spleen, and chronic diarrhea was present in varying degrees for six years. Eight years after the first injury he was thrown from a carriage and had a return of the same symptoms. Three months later he had an enormous internal hemorrhage. For three years the hemorrhages continued, at intervals. A diagnosis of diaphragmatic hernia with partial extrusion of stomach, dislocation of heart and pneumogastric fistulæ was made and verified by autopsy. During the illness of the patient relief from the extreme pain was given for a year by stomach lavage. By keeping the stomach clean the generation of gases had been prevented.

Treatment of Mediastinal Carcinoma by the X-Ray.

Dr. G. E. Pfahler, Philadelphia reported six cases following carcinoma of the breast, the first occurring in a woman, aged 36, sixteen months after removal of the primary growth. X-ray treatment was instituted and the patient is now able to do her ordinary work. The second case was a secondary growth appearing three years after the removal of the primary lesion. This was treated on several occasions for a period varying from six weeks to three months, and the patient has now apparently recovered. The third, fourth and fifth cases were women, aged, respectively, 62, 52 and 62 years, in whom the treatment was followed by good palliative results.

DISCUSSION.

Dr. Jay F. Schamberg, Philadelphia, said that in malignant disease surgical interference should be employed in operable cases, and the *x*-rays used as a postoperative measure and in inoperable cases as a palliative agent.

Dr. John C. Price, Scranton, emphasized the importance of careful individual regulation of the strength and quality of the rays, and deprecated the fact that they were too often employed by the general practitioner without sufficient regard to these facts.

Dr. Ernest Laplace, Philadelphia, believed that during the early stages of malignant diseases, if the cells were of a low grade, the *x*-ray possibly would destroy them.

Dr. Charles P. Noble, Philadelphia, stated that he believed that the field for this work was in postoperative and palliative measures, rather than in operable cases in the first instance.

Conservative Treatment of the Enlarged Prostate.

Dr. H. M. Christian, Philadelphia, stated that the patient when first seen by the surgeon would present one of the two conditions: (1) Good general health, moderate enlargement of the gland, with increased urethral length, partial retention, residual urine, varying from three to six ounces, urine sterile or slightly cloudy, indicating slight infection of the bladder. Catheter used without difficulty once or twice daily. (2) General health fair, marked enlargement and increased urethral length, complete retention, absolute catheter life, chronic cystitis and the introduction of the catheter difficult and painful. He did not view prostatectomy, either suprapubic or perineal, as a minor operation, and while recommending it for the second class, felt that its use should be limited to those cases in which there was acute or chronic cystitis, painful or difficult insertion of the catheter or the occupation of the patient prevented the use of this instrument. He stated that careful attention should be given to the selection and sterilization of the catheter and the instruction of the patient in its use, and considered the soft rubber and single or double elbow silk-woven instruments to be the only safe ones for home use.

DISCUSSION.

Dr. H. R. Gaylord, Buffalo, felt that the reason the mortality is so high in prostatectomy operations was due to the fact that the cases came too late. He believed that there is great danger from the continued use of the catheter, no matter how careful the patient might be, and urged operative interference, unless the cases were in too poor condition at the time they came to the surgeon to warrant this course.

Dr. Richard H. Gibbons, New York recommended operative interference, discussing various operations, including the Reginald Harrison and the Parker Sims method, and remarked that by the latter the largest prostate could be removed in a short time. He urged that the operation be done under cocain anesthesia as soon as a collar is discovered about the urethra.

Dr. William L. Rodman, Philadelphia, recommended that operative interference be the rule, rather than the exception, especially if the man is not more than 55 or 60. The operation of Hunter Maguire he considers the most appropriate one. The danger of infection or malignant disease is too great to warrant the continued use of the catheter.

Recent Results in Cancer Research which Bear on the Parasitic Theory.

Dr. H. R. Gaylord, Buffalo, reviewed the literature regarding the transplantation of tumors. He referred to one operation reported by Ehrlich, in which the tumor started by inoculation from a carcinomatous growth that at the thirteenth generation developed into a sarcoma. Spontaneous recovery took place in about 50 per cent. of the cases inoculated. He also referred to experiments made by injecting the serum from immune mice, or by mixing the blood of immune mice with the germ as prepared for inoculating others, which would prevent its taking any effect. He gave a detailed account of the experiments conducted under his direction with a view to proving the germ theory.

DISCUSSION.

Dr. Jonathan Wainwright, Scranton, referred to the possibility of curing cancer by means of the injection of serum from some immune person, and felt that the experiments would be very valuable, if such a serum could be obtained.

Dr. William L. Rodman, Philadelphia, congratulated the author on the work he had done, but felt that it was incumbent on the advocates of the germ theory of the origin of cancer to bring more evidence to bear on the point. As a contradiction of the germ theory he referred to the fact that there was no reported case of a physician becoming infected while doing an operation.

Dr. Ernest Laplace, Philadelphia, stated that he believed there were two things necessary to the development of cancer, a proper seed and a fertile soil; and that a receptive soil would develop the condition, while an unreceptive one would not.

Fractures of the Head of the Radius.

Dr. T. Turner Thomas, Philadelphia, stated that a search of the literature on this subject revealed only 48 reported cases, six of which were diagnosed during life; and that he had been able to secure from four skiagraphers in Philadelphia records of about 55 cases. He mentioned as important diagnostic factors interference with rotation and supination, localized pain and tenderness, together with a history of falling on the hand, and recommended as a treatment immobilization for three or four weeks, after which passive movements should be begun gently.

What Constitutes Operability in Cancer of the Uterus.

Dr. Ella B. Everitt, Philadelphia, stated that the best results would be accomplished in three ways: 1. By bringing about conditions favorable to earlier diagnosis. 2. By improvement in operative technic. 3. Clear and widespread knowledge of when to apply radical measures and when to be content with palliative relief. Among the factors requiring consideration under the latter heading are (a) the proportion of the uterus involved, (b) the extension behind the uterus, and (c) the operative measures available. The question of prime importance should always be what is best for this individual patient. Operative interference is justifiable only when a radical cure or at least a prolongation of life under more favorable circumstances can be expected.

(To be continued.)

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Thirty-first Annual Meeting, held at Indianapolis, Oct. 10-12, 1905.

(*Continued from page 1270.*)

Retroperitoneal Teratoma.

Dr. C. M. Nicholson, St. Louis, described a teratoma of the abdominal cavity, remarkable not only because of its rare occurrence, rapid growth, and total absence of symptoms until three weeks before death, but because with its substance had been found a chorion epithelioma. The following is the author's report of the case:

Aug. 5, 1905, he was consulted by C. W., a healthy-looking, well-developed young man, 21 years of age, who complained of one symptom—fainting—which had occurred twice during the preceding week. He had attended to his business until August 4, when he quit work, fearing an accident during his trips as superintendent down into the mine. On inspection the abdomen appeared normal; pressure over the region of the gall bladder enabled the examining finger to outline a pear-shaped body. In the median line beneath the rectus abdominis, extending from a point four inches above the pubes to the lower margin of the right lobe of the liver was an immovable mass of definite form. The line of dulness was continuous between the pear-shaped body and the mass in the median line. Although the growth measured four inches in width, no intestinal disturbance had resulted. Three weeks later the patient vomited and complained of great pain after eating. The vomiting became more frequent and the pain more severe with each succeeding day. He saw the patient September 3 and the following morning made an exploratory incision, revealing a growth extending from the right kidney to the last dorsal vertebra, thence downward to within two inches of the pubes. It was firmly attached to the median line posteriorly and to the kidney externally. The posterior peritoneum was cut through and the mass found to be enclosed in a fibrous capsule, which was sewed to the anterior layer of the peritoneum and a portion of the growth removed. The patient sat up at the end of the first week, but continued to complain of great pain. He died two weeks after the operation.

Postmortem examination was made by his assistant, Dr. S. S. Stahl, whose report in part is as follows: "On opening the cavity of the abdomen and cutting through the posterior peritoneum and transversalis fascia, a fibrous capsule enclosing a semi-solid mass and adherent only in the median line and to the right kidney, was found. Not without much difficulty could the tumor be removed, so intimately was it attached to the structure, anterior to the vertebral column. The abdominal aorta from the first dorsal vertebra to the fourth lumbar was closely attached to the growth. The gall bladder was distended, evidently due to pressure on the common duct. Neither the lumbar glands nor the kidneys were enlarged, although the right kidney was adherent to the tumor. The liver, though very slightly enlarged, showed evidence of involvement. The heart and pericardium were normal. The lungs contained 200 or 300 nodules."

The tumor weighed a little less than two pounds. It was right-angled and lobulated, the lobules being smooth and extending in different directions. On cutting, the tumor was soft, the anterior inferior extremity being partially cystic. Some of the cysts were as large as a hazelnut. The remainder of the growth appeared solid. The outer surface of the tumor was covered with a distinct fibrous capsule. Paraffin section of the Zenker fixed tissue showed a very complicated mass. Portions of organs were found corresponding in embryonic origin to all the germinal layers. Skin, cutaneous organs, central nervous system, peripheral nerves, represented the epiblast. Mucous glands, tubes, cysts with epithelial lining, were indicative of the hypoblast. Bone, cartilage, fibrous tissue, constituted the mesoblastic structure.

The author considered at length the different theories that have been advanced in the past to account for the origin of teratomata.

DISCUSSION.

Dr. Joseph Rilus Eastman, Indianapolis, said that he has had a remarkable experience in relation to tumors of this character. He has had two cases of precoccygeal teratomata, but no cases of inclusio fetalis, as he considered the case of Dr. Nicholson. In the first there was presented the clinical picture of a complete external fistula in ano. Long hairs protruded from both orifices, but when the roof of the canal was split up it developed that there was a cavernous space which was lined with epithelial membrane and this proved to be in either case a precoccygeal teratoma or dermoid. He related a case in which his father, the late Dr. Joseph Eastman, had removed almost a complete skeleton from the abdominal musculature in a man of middle age.

Dr. Nicholson said that chorion epithelioma in a retroperitoneal teratoma is extremely rare, and he has been unable to find a similar instance in the literature. Examination of the microscopic slides demonstrates clearly the presence of tissues from the three germinal layers.

Some of the Fallacies in the Clinical Diagnosis of Gonorrhea.

Dr. G. Frank Lydston, Chicago, discussed some of the more dangerous of the fallacies in the diagnosis of this disease, with especial reference to prognosis as regards the infectiousness of a given individual to other and healthy persons with whom sexual contact may occur. He considered, first, the possibility of excluding infectiousness in the case of a woman under suspicion, or who is known to have had gonorrhea. That the most dangerous type of infection of the female is that in which the external manifestations of the disease are absent or wanting, is coming to be well understood by both gynecologic and genitourinary specialists. The explanation of the relatively great danger of infection of others by such subjects is not so thoroughly understood as it should be. Gonorrheal urethritis in the female, when it has assumed the chronic form, may present no secretion whatever on external examination. There may be little or no vaginal, cervical or uterine discharge, and even such as there is might on examination fail to disclose the micro-organisms of gonorrhea. A swab or probe passed into the urethra may return perfectly clean. Notwithstanding this apparent lack of infection in the urethra, the mucous glands may be involved, and under the influence of sexual excitement and the mechanical effect of coitus, the physiologic hypersecretion may convey to the meatus gonococci in abundance. The result is sufficiently obvious.

The author presented clinical facts which would seem to make it impossible for a physician to say in a given case that a woman is free from infection. He thought this one of the strongest arguments against regulation and medical inspection of prostitutes. He entertains serious objections to the medical profession constituting itself an assurance society for the protection and promulgation of the social evil, but aside from this scruple there remains the fact that no reliable system of inspection or examination can be devised. He is firmly convinced that in many cases of infection of healthy women by a latent gonorrhea of the husband, mixed infection is responsible, and the resulting pathologic condition in the female is non-specific. Its being non-specific, however, does *not* preclude the possibility of its becoming very serious. We have no tests at the present time which will enable us to give a positive opinion of the infectiousness of a given case of suspected latent gonorrhea. As already suggested, the clinical history in many cases is more important than the laboratory study of the case, and a careful combination of both methods of study is always essential. The physician should be as chary of assuming responsibility in advising a gonorrheic in the matter of matrimony as he should be in advising syphilitics under similar circumstances.

Irritation of the Bladder.

Dr. A. Ravogli, Cincinnati, stated that in many abnormal conditions of the genitourinary organs and also of the urine itself, this affection comes on as a symptom in the form of frequent micturition. This symptom can be produced by a number of intravesical and extravesical affections. Urination is so increased that it seems the bladder can not tolerate the presence of urine. In some cases it occurs in the daytime only, in others at night, and in severe cases often in the day as well as in the night. The intervals between urination may be two hours, but in some cases the patient urinates every quarter of an hour, or even every five minutes. The patient loses sleep, wastes away, and is scarcely able to attend to his occupation.

In reference to the causes, the urine may be the cause of irritation on account of its quantity or its quality. It may be too concentrated, contain urates, phosphates, sugar, etc., which maintain or keep up irritation of the bladder. The bladder itself may be the cause on account of an hyperemic condition. This hyperemia may be the result of vesical or of extravesical troubles, phimosis, urethritis, prostatitis, neoplasms, pericystitis, vulvitis, nephrolithiasis, etc. In other cases it is a pure neurosis, the consequence of epilepsy, hysteria, eclampsia, etc. Since the urethroscope and the cystoscope have been in use, cases of irritation of the bladder without pathologic condition have greatly diminished, and in most of them there has been found either granulation or hyperemia of the mucous membrane. There are two kinds of irritation of the bladder, one of which is a local neurosis, and the other which results from pathologic alterations of the bladder or of the urethra. The detection of the causes will assist materially in selecting appropriate treatment.

Prostatectomy.

Dr. W. D. Haines, Cincinnati, said that two patients, aged respectively 42 and 59 years, with small indurated prostate with obstruction, occurring in his practice, did well after perineal section and the removal of the prostate gland, in that the catheter was abandoned and a troublesome cystitis relieved. One of the cases suffered incontinence for a period of three months after operation, and the cure was complete, as residual urine was found in both cases, and this despite easy bladder access by the sound or catheter. He condemns the use of metallic instruments in prostatics for diagnostic purposes, or for the relief of urinary retention, as the danger of perforation and infection far outweighs the meager information or temporary relief thus obtained.

One can hope for complete cure in 30 per cent. of the cases submitted to prostatectomy, namely, release from catheter bondage, relief from bladder complications and restoration of urinary function. In his experience with perineal prostatectomy seven cases have been functionally cured, nine show residual urine, some of whom have had attacks of cystitis and dribbling, and five of these are suffering from incontinence six months to one year and a half after operation. Two cases required secondary operation, one for stone, and one for perineal fistula, making a total of sixteen cases with ages ranging from 42 to 79 years without mortality. While these results are far from ideal, the unfavorable physical condition present in the majority of them will in a measure militate against criticism as to the final outcome of this series.

Operative Treatment of Tuberculous Joints.

Dr. Horace J. Whitacre, Cincinnati, advocates four kinds of operations for tuberculous joint disease. First, osteotomy for the removal of an epiphyseal focus; second, erasion or arthrectomy of those cases, particularly in the young, where the focus is circumscribed and a fair amount of synovial membrane remains; third, excision; fourth, amputation. Six cases of rather extensive tuberculosis of the knee were treated by arthrectomy or erasion. In four of these cases a complete cure of the disease with a useful stiff joint and good position was obtained. In three, a slight amount of motion, giving some assistance to the patient in locomotion, was regained. In two, amputation was subsequently resorted to. These subsequent amputations occurred in patients who passed from his observation very soon after operation. They undoubtedly represented recurrence in a spot where the dissection was not sufficiently thorough. Excision for a tuberculous joint has been reserved in his practice for those cases in which the bone ends are damaged.

President's Address.

Dr. Bransford Lewis, St. Louis, considered two subjects: 1, Some unrecognized responsibilities of press and state in conserving health; and 2, the prophylaxis of the so-called venereal diseases. He called attention to quack medical advertising in newspapers and magazines, and said that news managers provide against discrimination frequently by making unworthy advertisements resemble as closely as possible the regular news material of the paper, or by setting it up as telegraphic matter. He thinks the press is *particeps criminis* in presenting such fraudulent material. There is a widely disseminated and growing belief that matters pertaining to sexual physiology and pathology should be taught in a simple way to the budding youth of both sexes in the course of their regular education, in order to place them in a position to resist the temptations that beset young life, by the clearer understanding that such instruction will afford. He would make use of educational channels of all sorts to spread the information desired in a scientific, dignified, truthful and wholesome manner, and such instruction will be received in the spirit in which it is imparted. It is primarily to the education of the people to which we must look for providing either the required legislation or the belated impulse or self-respect and decency on the part of the newspapers in eliminating quack advertisements.

Another subject which he considers well worthy of attention is the determination of practical methods of protecting the people from the far-reaching and disastrous effects of those diseases generally termed venereal, but which are not uncommonly entirely innocent in their development. He referred to gonorrhea, syphilis and chancroid. These diseases prevail to an extent undreamed of by the people and those in control of the public health of the country. He believes nothing is to be accomplished by prolonging a discussion as to the propriety of legal control and the regulation of prostitution. Instead of trying to do what is impossible, to corral and disinfect all prostitutes, he would teach the public the dangers of prostitution, the dangers of the diseases to which it leads, the prevalence of such diseases in daily life, how they are acquired innocently, how they are to be avoided, and the necessity of seeking relief from them as soon as possible when they are acquired. A campaign of education must be the chief reliance, and the medical profession, followed by the ministry, instructors in institutions of learning in general, philanthropists and leaders in public work, will have to be counted on as the purveyors of such education.

Present Status of Surgery of the Stomach.

Dr. W. D. Haggard, Nashville, Tenn., said that a discussion relative to operation for stomach lesions now is similar to that in regard to appendicitis twelve or fifteen years ago. Then only the desperate cases were submitted to operation. It is so now with many stomach cases. This, however, must yield to the logic of results, and in a short time the profession generally will advise early operation as they now well nigh universally do in appendicitis. Improved technic, low mortality and satisfactory end results will inevitably do away with the empirical treatment of occult intractable stomach troubles. The typical indication for operative interference is obstruction of the pylorus from an open or cicatrized ulcer causing dilation of the stomach, with stasis of food. The short circuiting operation of gastroenteric anastomosis finds its ideal operation here, and has given the most beneficent results. It is the *fons et origo* of the present group of drainage operations, as well as other gastric procedures, and is altogether the most perfected and satisfactorily employed operative device. The other complications of ulcer requiring operation were pointed out, as (1) perforation, (2) hematemesis of chronic ulcer. Operation is advised in repeated acute hemorrhage or in constantly recurring small hemorrhages. Other indications are found in the following groups of cases: (3) Obscure and persistent stomach troubles, with a long history of dyspepsia culminating in hemorrhage after it has been controlled by medical means and the patient put in the proper condition for operation. (4) Cases of chronic intractable dyspepsia, even without dilatation, which fail to yield to proper medical treatment and are not due to a general visceral ptosis.

Aside from malignancy, chronic ulcer and its complications furnish most of the indications and the majority of cases. It is not impossible that the bulk of cases of inveterate dyspepsia is really due to ulcer. That it is found postmortem very many more times than it is recognized clinically.

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.

Fourteenth Annual Meeting, held in Detroit, Sept. 26-28, 1905.

(*Continued from page 1195.*)

Delegates.

Among the foreign delegates accredited to the association were: Surgeon-General S. Suzuki, imperial Japanese navy; Drs. M. W. P. Chung, chief surgeon Chinese Government Hospital; Tsin Ying Young, surgeon-major imperial Chinese army, and Ho Kan Yuen, chief surgeon imperial Chinese navy; Col. H. Mareschal, surgeon in the French service; Lt.-Col. J. T. Fotheringham and Maj. E. B. Echlin, of the Canadian medical service; Col. William John Read Rainsford, Royal Army Medical Corps; Fleet Surgeon F. Lloyd Thomas, Royal Navy, and Lt.-Col. Alejandro Ross, of the Mexican Army. Brigadier-General C. H. Todd, Owensboro, Ky., president of the Association of Medical Officers of the Army and Navy of the Confederacy, was also present as delegate from that association.

Honorable Mention.

In the competition for the Seaman prize the papers of Maj. Frederick Smith, R.A.M.C., Major Charles E. Woodruff, surgeon, U. S. Army, and Assistant Surgeon William Colby Rucker, United States Public Health and Marine-Hospital Service, received honorable mention, in the order named.

Senn's Welcome.

Col. N. Senn, Surgeon-General of Illinois, founder of the association, held an impromptu reception at the first meeting of the association on his return from a summer spent in Greenland and the arctics with Commander Peary's expedition.

Captured at Mukden.

Col. Valery Havard, assistant surgeon-general, U. S. Army, military attaché with the Russian army in Manchuria, who was captured when the Russians evacuated that place, was present and interestingly detailed his experiences.

The Stokes-Seaman Controversy.

One of the most exciting features of the convention was the attack made by Surgeon Charles F. Stokes, U. S. Navy, on Major Louis L. Seaman, U. S. V., in which he bitterly arraigned Major Seaman for misstatements and misleading figures in his paper read last year before the association at St. Louis. He charged that Major Seaman's assertion that the proportion of loss by gunshot wound to the loss by disease in the Spanish-American war in a campaign lasting but six weeks was as 1 to 14 was incorrect. He stated that the report of the Secretary of War for 1898 shows that 270 died of wounds and 400 of disease in that campaign, a proportion of 1 to 1½. Dr. Seaman placed the losses from disease at 3,862. He also made the proportion of battle casualties to disease in the Civil War as 1 to 5, while the proportion, as shown by the official history, was 1 to 2. Dr. Stokes also attacked Major Seaman's statement that beri-beri was almost unknown among the Japanese and produced figures showing that of 5,609 cases of illness among Japanese troops in Manchuria 5,070 were of beri-beri, that the loss to the effective forces of the Japanese before Port Arthur from beri-beri alone was 25,000, and that in the second Japanese army of three divisions with 19,000 men in each there was a sick list of 24,642 in seven months, figures not varying greatly with those of other armies under similar conditions. He also attacked Dr. Seaman's knowledge of bacteriology, military hygiene and principles of aseptics and antiseptics.

Dr. Seaman was not present when this arraignment was made, but prefaced the reading of his paper by a caustic reply to the charges. He claimed that Surgeon Stokes had emasculated the extracts from his writings and addresses which had been quoted, gave the source of every statement and of all the statistics for which he was criticised, and made a strong argument, not against the personnel of the medical department of the army, but against the lack of business system under which the medical department was conducted, which, he said, was responsible for many of the abuses and for the bad record as regards illness made in the Spanish-American war.

The Real Triumph of Japan.

Major Louis Livingston Seaman, U. S. V. E., in an interesting paper, entitled "The Real Triumph of Japan, or the Conquest of the Silent Foe," stated that, without minimizing the splendor of Japan's victories on land or sea, he must unhesitatingly assert that the greatest conquests of Japan were the humanities of war in the stopping of needless sacrifices of life by disease, and that this had been done by the medical men of the army.

"It must never be forgotten," said Major Seaman, "that in every great campaign an army faces two enemies: First, the armed forces of the approaching foe, with its various machines for human destruction, that is met at intervals in open battle, and, second, the hidden foe always found lurking in every camp—the far greater and silent foe—disease."

Quoting from Longmore's tables, which are accepted as the most reliable statistics of war, he showed that for two hundred years there has rarely been a war where at least four men have not died from disease to one from bullets. In the war between Turkey and Russia in 1878, 80,000 men died from disease and 20,000 from wounds. In the Crimean war the allied forces lost 50,000 men from disease and 2,000 from wounds. In the Civil War the ratio was about 4 to 1, and in the Boer war the losses of the English from disease were appalling. In the Russian-Japanese war 52,946 men in the Japanese army were killed or died from wounds, while but 11,992 died from disease, or nearly 5 to 1.

Japan accomplished this unparalleled record by organizing, in anticipation of war, her medical department on broad, generous lines and by giving to its representatives the rank and power which their great responsibilities merited. Japan even graded her medical men as high as officers of the line and accorded them equal authority, excepting, of course, in the emergency of battle. At home she organized the most splendid system of hospitals that has ever been devised for the treatment of sick and wounded, and put into execution a more effective system of sanitation than has ever been practiced in war. He contrasted with the complete preparatory work of the Japanese medical department the action of the hero of Manila in censoring the cablegram of the chief surgeon, who had requested fifty additional medical officers and two hundred more nurses when the hospital wards were overcrowded, because such a dispatch would prove the incorrectness of his claim that he had the situation well in hand. He also cited the recalling of the order at Tampa in the Cuban campaign directing the unloading of a ship filled with medical and hospital supplies for Santiago and the substitution therefor of a load of mules. He then detailed the incident of another general officer during the Spanish-American war who, when waited on by medical officers with a protest against the use of certain water supplied to the troops, said, "When I want your advice I will send for you. Until I do, you can attend to your own business." Lastly he narrated the incident of the Secretary of War who, when inspecting Camp Wyckoff, Montauk Point, with the President, said, on looking at a glass of water, furnished the troops in this infected camp, which had been pronounced by medical officers to contain germs of disease, "Why, it looks all right to me."

The only relief that can come to these conditions of health in the U. S. Army is when the medical officers are given more authority and when the actions of young and inexperienced officers are allowed to interfere less with the workings of the medical corps. When they listen more to the advice of men like Surgeon-General Sternberg, then many of the faults of the present system will be changed.

"Until the line and staff officers of the U. S. Army," said Major Seaman, "are taught the necessity of sanitation and the medical officer is given rank and authority to enforce it, the medical department of the army must remain a humiliating failure. Its continuance under present conditions is no less than an evidence of national imbecility."

Major William C. Borden, U. S. Army, stated that it is a melancholy admission, but that he feared, were war to come on the United States at this time, the medical department of the army would make little better showing than in the Spanish-American war. The medical force to-day is large enough for an army of 42,000, while sufficient officers are provided in the other branches of the service for an army of 100,000. "The war department," said Major Borden, "detailed five officers to accompany the Russian and Japanese armies to observe the latest method for killing, but not one to observe how lives are saved by preventing disease until the President's attention was called to it by an interview with Major Seaman, whereon he directed a surgeon with the rank of colonel to be detailed as attaché in Manchuria, which was done."

Major Charles T. Newkirk, Bay City, Mich., made an ardent defense of General Alger, and stated that in his experience in the Spanish-American war he had had no trouble in getting what he wanted from the medical supply depot and claimed that the United States had the finest army in the world and the best physicians.

Major Carlton E. Starrett, Elgin, Ill., urged that reform was needed in the medical service and cited the experience in Camp Thomas, Chickamauga, when, before the camp was a month old, the medical department had condemned it as unsanitary; but the recommendations of the medical officers counted for naught. In Porto Rico he stated that a regiment was put into an unhealthy camp, and that the medical department condemned the camp, but that until half the regiment was ill the camp was not moved.

Col. William J. R. Rainsford, R. A. M. C., spoke of the benefits to the medical department to be derived from criticism and publicity. He stated that if you educate the people you will get what you want, and not until then; that not until the public knows what is needed will the appeal be answered. He cited the criticisms of W. Ashmead Bartlett on the British medical department in the South African campaign, for which the medical department hated him. He published reports which the medical department did not like, but it was through these reports that the public became interested, and this resulted in the reform which was necessary, and which has now been attained, whereby the abuses in the medical department have been abolished and the condition of the officers of the Royal Medical Army Corps greatly improved. "So," said Colonel Rainsford, "to the man who stirred up ill feeling we owe the reforms which we got."

American Nurses in Japan.

Dr. Anita Newcomb McGee made an interesting report of her work and observation while in charge of a party of American nurses at Hiroshima Hospital, the largest military hospital in Japan. She confirmed the reports previously made that the wounded prisoners received exactly the same treatment as the wounded Nipponese, and that in its organization and practical workings the Red Cross service of Japan was far ahead of that of any other nation with which she was familiar.

(To be continued.)

AMERICAN ROENTGEN RAY SOCIETY.

Sixth Annual Meeting, held in Baltimore, Sept. 28-30, 1905.

Under the Presidency of Dr. Charles Lester Leonard, Philadelphia.

Study of Stomach and Intestines.

Dr. Henry Hulst, Grand Rapids, Mich., spoke of the value of the Roentgen ray in the diagnosis of dilatation and dislocation of the stomach and intestines. To obtain a radiograph of these organs, an ounce of bismuth is given in a pint of milk or potato soup. Two exposures are made: one in the erect and one in the recumbent position. The first is made shortly after the ingestion of the bismuth and the second is made six hours later, thus showing the size, shape and functional capacity of the stomach. If a good picture of the colon is not obtained in this way, three ounces of bismuth should be injected per rectum.

Interpretation of Lung Negatives.

Dr. George E. Pfahler, Philadelphia, said that in order to study the lungs accurately the negative must be made while these organs are at rest. A careful physical examination should precede the Roentgen examination to permit of a correct interpretation of shadows. In tuberculosis, the Roentgen ray is an aid in diagnosis and also records the progress the disease is making.

Dr. Hulst considers the Roentgen ray as a means of diagnosis of pulmonary tuberculosis of equal value as the sputum examination.

Diagnosis of Aneurisms.

Dr. F. H. Baetjer, Baltimore, believes the Roentgen examination of aneurisms far superior to any other method of examination. The diagnosis can be made earlier and more correctly, thus permitting earlier and more effective treatment. A physical examination should precede the Roentgen examination so as to detect any deformities that may exist and that would make the diagnosis of aneurism more difficult. He said that a pulsating shadow that does not disappear between pulsations is always suspicious.

President's Address.

Dr. Charles L. Leonard reviewed the past, present and future of the Roentgen ray, its identity, chemistry and physiologic action and application to medicine.

Regulation of Dosage of Roentgen Ray.

Dr. E. G. Williams, Richmond, said that the more superficial the effect desired, the closer the tube should be placed to the surface. He found that about ninety minutes' exposure, with a tube distance of ten inches, spark gap of four inches equivalent to the resistance in the secondary circuit, and the millimeter showing three-fourths of a mp., is required to produce an erythema of the surface. The safety limits are about 30 per cent. less than the number of minutes required to produce a decided erythema. The law of inverse squares helps in regulating the exposure and distance of the tube from the surface. Williams' rule is not to expose in ten days more than the number of minutes required to produce a dermatitis, giving the treatments in series of four to six exposures. To measure and record the dose of the *x*-ray, there should be noted the duration of the exposure, the distance of the surface from the platinum disc, the equivalent spark gap and the reading of the millimeter.

Roentgen Treatment of Keloids.

Dr. O. S. Barnum, Los Angeles, Cal., uses an abundance of rays emanating from a tube of high resistance and excited by a large coil. It is better to have the tube too high than to have it too low. The tube distance should be fifteen to twenty inches, depending on the thickness of the tumor. The thicker the tumor, the higher the tube, the greater the distance and the longer the exposure. He usually exposes for from fifteen to twenty-five minutes on alternate days for ten days, and then stops treatment for ten days, repeating this procedure until the tumor has disappeared. He has had excellent results in the treatment of keloids by this method.

Drs. Boggs, Pancoast and others favored preliminary excision of the tumor, whenever this is possible, following this with Roentgen treatment. The tumors disappear more rapidly and are not so liable to recur.

Present Status of Radiotherapy.

Dr. G. G. Burdick, Chicago, cited cases to show the efficiency of the Roentgen ray in the treatment of skin lesions, many of which are cured entirely, while others are only improved. He has treated eighty cases of epithelioma involving the skin only without a recurrence. In cases of epitheliomas situated at muco-cutaneous junctions he advised removal of the glands in the vicinity after a period of quiescence has been brought about by Roentgen treatment. This method was followed in twenty-three cases with no recurrence of the disease after two years. The knife should be used only in such cases where the tumor is favorably situated for a radical removal. Eighteen cases of carcinoma were cured. In fourteen cases the tumor and enlarged glands disappeared completely; in four cases they ceased growing. His results in the treatment of sarcoma have been as successful. He believes that every case of primary sarcoma can be much benefited by prolonged mild radiation from an old tube well plated with aluminum.

Treatment of Carcinoma.

Dr. George C. Johnston, Pittsburg, said that in carcinoma of the breast the application of a ray of sufficient intensity for a sufficient length of time is capable of causing a disappearance of the tumor. The course of radiation should not exceed ten treatments of twenty minutes' duration each, with a tube distance of eighteen inches. A tube of fairly low vacuum should be used, carrying a current not to exceed two and a half mp. On about the fifteenth day after operation, postoperative radiation should be begun, raying through the dressings every other day for ten minutes at a time.

Dr. George H. Stover, Denver uses a ray of mellow quality that will penetrate the tissues, exposing the surrounding tissues for a reasonable distance from the tumor. All vulnerable parts should be protected from the ray. He makes applications three times a week for ten minutes at a time, the tube distance being eight to ten inches. He advises the use of the Roentgen ray in all primary non-operative and recurrent non-operative carcinomas. While there is an equal chance, operation should be done first, followed by Roentgen treatment.

Treatment of Sarcoma.

Dr. William B. Coley, New York, said that the value of postoperative treatment of sarcoma has not yet been determined. The facts up to the present time fail to show that the Roentgen ray is curative of malignant growths, except those that are superficial. In some cases the tumor decreases in size, and in a few instances it has disappeared entirely. In all the cases he has treated there has been either local or general recurrence, although in some few cases life has been prolonged. The universal tendency to recurrence and the danger of dissemination of the tumor is sufficient reason, in his opinion, for not advocating the Roentgen ray in the treatment of these tumors, except in inoperable or recurrent cases.

Calculus Diagnosis.

Dr. Russell H. Boggs, Pittsburg, described his method and technic for diagnosing renal and ureteral calculi. The radiograph should be made while the patient holds his breath, using a large amount of current for a short time. In over 200 cases examined there were only two unsatisfactory results.

Drs. Pancoast, Smith and others pointed out that the calcified lymph glands, phleboliths and calcareous deposits in the broad ligaments and pelvic fasciæ may make a shadow simulating a ureteral calculus. Dr. Kassabian advised inflating the urinary bladder with air to assist in making a diagnosis of stone in the lower ureter.

Dr. Pfahler exhibited a new Roentgen ray filter consisting of a piece of sole leather which is moistened so as to resemble normal skin as much as possible. A piece of silver may also be used.

Dr. Strong, Boston, exhibited a unipolar *x*-ray tube to be used for the treatment of the center of tumors and growths on the walls of cavities.

Officers Elected.

The following officers were elected for the ensuing year: President, Henry Hulst, Grand Rapids, Mich.; vice-presidents, Russell H. Boggs, Pittsburg; C. E. Skinner, New Haven, Conn.; E. G. Williams, Richmond, Va.; E. W. Caldwell, New York; secretary, George C. Johnston, Pittsburg; treasurer, L. E. Custer, Dayton, Ohio; members of executive committee, P. M. Hickey, Detroit, and J. F. Smith, Chicago.

Chicago was selected as the next place of meeting.

The following papers were also read: Skeletal Development, P. M. Hickey, [illegible] kemia, J. F. Smith, Chicago; Roent[illegible] Disease, Leukemia and Polycythemia, [illegible] Treatment of Lupus and Rodent Ul[illegible] l; Treatment of Non-malignant and [illegible] is, W. S. Newcomet, Philadelphia; [illegible] urgery, C. F. Stokes U. S. N.; Pathologic and Physiologic Effects of the Roentgen Rays, J. Rudis-Jicinsky, Cedar Rapids, Iowa.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Cardiac Affections.

Lambert, in the *New York State Journal of Medicine*, states that we must regulate the patient's exertions and the patient's environment rather than nag the heart with drugs. If the compensation is broken, then rest in bed should be ordered; if dilatation has taken place, some drug of the digitalis group must be used to lengthen the diastolic pause by diminishing the number of systoles, and thus increasing the time for cardiac nourishment. Small doses of the powdered leaves of digitalis with the extract of gentian are the least liable to disturb the stomach. A grain of digitalis leaves in twelve hours is often sufficient and is better than larger doses. One can divide this grain in varying amounts at varying intervals in the twelve hours. Strychnin sulphate or tincture of nux vomica is often of great value. When there are atheromatous changes in the blood vessels small doses of potassium iodid are of benefit. In order to avoid upsetting the digestion the author recommends giving the drug in a mixture containing aromatics and some artificial digestive substances. A dose of 5 gr. (.3) three times a day is usually sufficient. It is necessary to maintain a good digestion and thus aid in preventing arterial changes.

In the cardionephritic cases the author states that if the heart has reasonable compensation it should be left alone and the kidneys treated; if the heart is out of compensation it should be treated and the kidneys left alone for the time being, if they are doing a reasonable amount of work. The excessively high arterial pressure is often relieved by the administration of glonoin or sodium nitrite. The reduction of the arterial pressure will often relieve both the cardiac strain and the nephritic incompetence.

Brunton, in the *London Practitioner*, discusses breathlessness, especially in relation to cardiac disease. He states that digitalis is first in importance in its action on the heart and that there is no better way of giving it than the old-fashioned pill.

M. Ft. pil. No. i.

This is the most common formula, but occasionally an additional grain of blue pill is added to it, and sometimes the extract of hyocyamus 2 grains (.12) in each pill. Why the blue pill should help the action of the digitalis one can not tell, but there can be no doubt whatever that it does so. Of the other preparations, the infusion and the tincture are the most commonly used. The preparations vary in strength and must be given with caution in order to learn the action. In patients in whom digitalis does not succeed strophanthus proves efficient and vice versa. Those cases can only be determined by trial. One of the most valuable remedies for strengthening the heart is strychnin. Its action appears to be that of stimulating the cardiac ganglia, and in cases in which one is doubtful about giving digitalis or strophanthus, either because of their power of slowing the heart or of unduly raising the tension, recourse may be had to strychnin. At the same time this drug proves a most useful adjuvant both to digitalis and strophanthus, and may be given either by mouth or subcutaneously. When the heart is failing digitalin and strychnin may be employed subcutaneously together, and 1/2 or even 1 mg. (gr. 1/60) of the former with 1/30 or even 1/20 of a grain of the latter. Citrate of caffein in doses of from 2 to 5 gr. or diuretin in doses of from 2 to 10 gr. every six hours, are sometimes useful adjuncts to digitalis or strophanthus. Sometimes these drugs cause irritation of the stomach or bowels, and give rise to vomiting or diarrhea, which may require their discontinuance, and as a rule the author thinks they do more good if used only for a week or even less, and an interval of some days allowed before they are given again.

One of the most important means of relieving dyspnea is certainly free purgation, and one of the best means of securing it is by the use of compound jalap powder in doses of from 20 to 60 gr. (1.3 to 2). This combined with digitalis and blue pill, already mentioned, increases the elimination of water both by the bowel and by the kidney, and lessens the congestion of the liver, which is the natural consequence of venous stagnation. It also relieves the tendency to an edematous condition of the lung and eases respiration.

Furunculosis.

Guthrie, in the *Pennsylvania Medical Journal*, recommends the following treatment for this condition. He divides the treatment into preventive, abortive and curative:

PREVENTIVE.

Measures should be adopted to restore normal vitality, e. g., rest, recreation, fresh air and good food. Proper care should be given to the skin by bathing, and attention to slight injuries, so as to prevent ingress of pyogenic cocci. Sulphid of calcium has been advised as a measure to prevent boils, but the author has not obtained any good results from its use. He recommends the use of quinin in 3 gr. doses (.20) three times a day, given for a week, and claims excellent results.

ABORTIVE.

The author discusses the use of a saturated solution of permanganate of potassium applied to the furuncle and the insinuation into the hair follicle of a minute drop of clear carbolic acid, also the application of carbolic acid after an incision, and his conclusion is that the abortive treatment does more harm than good. All the methods employed involve the breaking down of the wall of protection against the infection. Care should be taken in the early treatment not to drive the infective agents deeper into the tissues nor to overdistend the pus cavity so that the septic process is made to spread.

CURATIVE.

He condemns the old-fashioned flaxseed and bread and milk poultices, believing they do more harm by softening and preparing the soil for the reception of infection. The so-called antiseptic poultice, such as gauze saturated with boric acid solution, or with Thiersch's solution, he considers an admirable dressing. As soon as the crater-like opening at the summit of the cone will admit a probe or small grooved director, and there is evidence of pus beneath, a small straight bistoury may be inserted and the opening enlarged so as to permit a free escape of any retained pus. This will give great relief to the patient. Day by day the softened slough or core may be gently pressed out by using cotton sponges saturated with boric acid solution or a weak bichlorid of mercury solution, and when the cavity is cleansed healing will take place very promptly. No free incision, no curetting or injections into the cavity will render any more satisfactory service, but will aggravate and prolong rather than shorten and relieve the trouble.

Camphorated Phenol.

Longenecker, in the *Pennsylvania Medical Journal*, discusses the use of this product in infected wounds.

Bufalini recommends the combination of carbolic acid with camphor under the name of camphorated phenol, asserting that the camphor moderates the caustic and disorganizing character of the phenol without destroying its useful effects. This mixture is composed of camphor 2 parts and carbolic acid 1 part. On being rubbed together, or simply left to stand and shaken occasionally a clear solution is formed. The formula in the U. S. Dispensatory directs that this solution be washed in water, but for what reason is not stated. The author thinks this washing can be omitted, as at the present day both camphor and phenol may be obtained in sufficient purity for our use without further purification.

The solution has a specific gravity of 1006, is non-corrosive and non-toxic to wounds, and can be applied in many conditions. The results following its use are most excellent in all cases. No untoward symptom has ever, in the author's experience, resulted from its application. Gangrene of the finger has frequently been reported as following the use of weak solution of carbolic acid and water, but this has never occurred even with this full strength solution, which contains 33 per cent. carbolic acid.

The application of camphorated phenol is almost without limit. It can be applied alike to sound skin, wounds and mucous surfaces, such as mouth, nose, vagina, or to abscess cavities, in its full strength and painlessly. Its only limitations seem to be the eye, ear and urethra; to these parts he finds the burning produced by it is rather unpleasant but of short duration, and it may be advisable to use less than full strength, although he has frequently applied it over a limited area even to these parts by the use of cotton on an applicator, in its full strength, without inconvenience to the patient. Camphorated phenol is soluble in alcohol and ether, but insoluble in water. It is miscible with oils and with some other substances, such as tincture of iodin and ichthyol, which serve to modify its action and widen its field of usefulness. Ease of preparation and cheapness are also greatly in its favor.

Flatulence.

Le Progrés Medical recommends the following formula:

℞.	Sodii bicarbonatis		
	Magnesii carbonatis, āā.................	ʒi	4
	Pulv. rhei		
	Olei fœniculi		
	Olei cari		
	Olei menth. pip., āā.....................	ʒss	2

M. Ft. pil. No. xx. Sig.: Two pills to be taken after each meal.

Medicolegal

Records of Free Hospital Patients.—Chapter 330 of the Acts of Massachusetts of 1905 provides that hospitals, supported in whole or in part by contributions from the commonwealth or from any municipality, incorporated hospitals offering treatment to patients free of charge, and incorporated hospitals conducted as public charities, shall keep records of the cases under their care and the history of the same in books kept for that purpose. Such records shall be in the custody of the person in charge of the hospital, and shall be admissible as evidence in the courts of the commonwealth as to all matters therein contained. But Section 17 of Chapter 35 of the revised laws declaring public records to be open for inspection shall not apply to such records, and they shall not be open to public inspection until they are produced in court by the person having the custody of the same.

Hospital for Prisoners Having Tubercular Disease.—Chapter 355 of the Acts of Massachusetts of 1905 provides that, with the approval of the governor and council, the board of prison commissioners shall have authority to erect, on the land now occupied by the temporary industrial camp for prisoners at Rutland, suitable buildings to be used as a hospital prison for the confinement and treatment of prisoners having tubercular disease. When such buildings are ready for occupancy the prison commissioners may remove thereto any male prisoner in the state prison, the Massachusetts reformatory, the state farm, or in any jail or house of correction, who appears by the certificate of the prison physician to be suffering from consumption or any disease of a tubercular nature. They may at any time return to the original place of imprisonment any prisoner so removed. A prisoner shall be held in the place to which he is so removed or returned according to the terms of his original sentence. A prisoner removed to said hospital prison shall be held in the custody of the superintendent of said temporary industrial camp for prisoners, and shall be governed, employed and treated according to such rules and regulations as may be established by the board of prison commissioners with the approval of the governor and council. Prisoners held in said hospital prison shall be subject to all the laws that are now applicable to the temporary industrial camp for prisoners.

Lighting, Heating and Ventilating School Buildings.—No. 193 of the Laws of Pennsylvania of 1905 provides that, whereas it is of great importance to the people of that commonwealth that public-school buildings hereafter erected shall be properly heated, lighted and ventilated, no schoolhouse shall be erected to cost more than $4,000 until the plans and specifications for the same shall show in detail the proper heating, lighting and ventilating of the building. Light shall be admitted from the left or from the left and rear of class-rooms, and the total light area must, unless strengthened by the use of reflecting lenses, equal at least 25 per cent. of floor space. School-houses shall have in each class-room at least fifteen feet of floor space, and not less than two hundred cubic feet of air space per pupil, and shall provide for an approved system of indirect heating and ventilation, by means of which each class-room shall be supplied with fresh air at the rate of not less than thirty cubic feet per minute for each pupil, and warmed to maintain an average temperature of 70 degrees Fahrenheit during the coldest weather.

Some Provisions for State Department of Health.—No. 218 of the Laws of Pennsylvania of 1905, entitled "An act creating a department of health, and defining its powers and duties," provides that such department shall consist of a commissioner of health and an advisory board of six members, to be appointed by the governor, with the advice and consent of the senate. The commissioner of health, who shall be the head of the department, shall be a physician of at least ten years' professional experience, and a graduate of a legally constituted medical college. The term of office of the commissioner first appointed shall expire March 1, 1907, and the term thereafter shall be four years. The commissioner is to receive an annual salary of $10,000, and expenses actually and necessarily incurred in the performance of his official duties. Of the advisory board a majority shall be physicians, graduates of legally constituted medical colleges and of at least ten years' experience in the practice of their profession, and one shall be a civil engineer. They are to receive no salary, only actual traveling and other expenses while engaged on the actual duties of the board. On the appointment and qualification of the commissioner, the terms of the members of the state board of health and the secretary of such board shall expire, and no appointments shall thereafter be made to those offices. It shall be the duty of the advisory board to advise the commissioner on such matters as he may bring before it, and to draw up such reasonable orders and regulations as are deemed by such board necessary for the prevention of disease and for the protection of the lives and health of the people of the state, and for the proper performance of other work of the department of health. The commissioner may employ such clerical and other assistants as are necessary and distribute appropriate powers and duties to employes of the department. He may also, from time to time, employ competent persons to render sanitary service and make or supervise practical and scientific investigations and examinations requiring expert skill, and prepare plans and reports relative thereto. It shall be the duty of the commissioner to protect the health of the people of the state, and to determine and employ the most efficient and practical means for the prevention and suppression of disease. He shall cause examination to be made of nuisances or questions affecting the security of life and health in any locality, and shall have power to order nuisances detrimental to the public health, or the causes of disease and mortality, to be abated and removed, and to enforce quarantine regulations. It shall be the duty of the commissioner to have the general supervision of the state registration of births, marriages, deaths and diseases; of practitioners of medicine and surgery; of midwives, nurses and undertakers, and of all persons whose occupation is deemed to be of importance in obtaining complete registration of births, deaths, marriages and disease. In order to insure the official registration of vital statistics and the management of the sanitary affairs of the different parts of the state, he may apportion the latter into ten districts and appoint a health officer in each who shall be a physician of at least five years' professional experience, a graduate of a legally constituted medical college, and who shall receive an annual salary of $2,500 and necessary expenses. The commsisioner may revoke or modify any order, regulation, by-law or ordinance of a local board of health, concerning a matter which, in his judgment, affects the public health beyond the territory over which the local board has jurisdiction. He is also to have all the powers conferred, and perform all the duties heretofore imposed by law on the state board of health, or any member, committee or officer thereof, including the secretary.

Additional Alcoholic Compounds to be Taxed.—Referring to Internal Revenue Circular No. 673, reported on page 1025 of The Journal of Sept. 30, 1905, James C. Wheeler, Acting Commissioner of Internal Revenue, rules, under date of October 9, that, although the ruling in Circular No. 673 has special reference to compounds composed of distilled spirits and drugs or other medicinal substances, yet in spirit and meaning it may also be extended to include other alcoholic liquors; and as fermented malt liquor, of which every malt extract is largely composed, is an alcoholic liquor, it is for the manufacturers of every such malt extract to show that it comes within that clause of Circular No. 673 in which it is stated that "where substances *undoubtedly medicinal* in their character are combined with . . . alcoholic liquor and are used in sufficient quantity to give a medicinal quality to the liquor other than that which it may inherently possess, such compound is, of course, not to be included in this ruling." In answer to an inquiry by a druggist, Mr. Wheeler further rules that the ruling of Circular No. 673 *does not apply to toilet* articles, whatever the quantity of alcohol contained therein may be; nor does it apply to the various essences or extracts sold as essences of lemon, vanilla, cinnamon, etc., if these preparations are such as are known to the legitimate grocery or drug trade as household articles for culinary and other uses, and not as beverages. Where, however, alcoholic compounds called "essences of lemon, vanilla, cinnamon," etc., or so-called tinctures or essences of ginger contain "a mere trifle of medicament, the main constituent being alcohol," and these preparations, "usually sold by country merchants, especially in prohibition districts," are found by the local internal revenue officers or agents to be generally sold or used as beverages, every merchant thus selling them without holding the requisite special-tax stamp as a liquor dealer under the internal revenue laws will be liable to criminal prosecution in addition to the assessment against him of special tax and penalty; and the manufacturers of these so-called essences and extracts, who are shown by the facts elicited to have made these alcoholic compounds for sale in prohibition districts, will be held liable to special tax and penalty as rectifiers and liquor dealers.

5 *Seven Cases of Bilharzia Hematobium. C. A.. Smith, Atlanta, Ga.
6 *Hemorrhagic Typhoid with Typhoid Parotitis, Recovery. B. D. Black, Las Vegas, N. M.

1.—See abstract in The Journal, July 29, 1905, page 347.

2. Quarantine, the Delirium Ferox of American Sanitation.—Fulton discusses the "quarantine madness" prevalent in the Gulf states during the yellow-fever epidemic. He believes that rational, uniform and effective inland quarantine, such as can only be obtained through the medium of the federal government, would reduce to insignificant proportions or perhaps abolish forever the detention camp, military cordon and other costly features of inland quarantine and would concentrate the more intense activities on and immediately around the infected areas.

3. Insomnia and Its Treatment.—Christison enters into a full discussion of the short periods of sleep among men of eminence; the phenomena of exhausted soldiers marching while sound asleep; the control of sleep by the will; age in relation to length and depth of sleep; quantity of food and the seasons of the year in relation to sleep; some long sleepers; sleeping sickness; suspended animation in man and animals; effects of forced privation of sleep; habits of sleep in animals—day and night sleepers.

5. **Bilharzia Hematobium.**—Smith reports seven cases found among the Boers and the South African negroes who were with the Boer War Spectacle at St. Louis during the World's Fair. The seven cases were apparently chronic, as macroscopic inspection did not indicate the presence of any blood or blood clots in the urine.

6. **Hemorrhagic Typhoid with Typhoid Parotitis.**—Black reports a case ending in recovery. The patient gave a history of an arrested pulmonary tuberculosis. There was no hemophilia or syphilis. The patient was a total abstainer. Hemorrhages occurred about the seventeenth day of illness. Intestinal oozing was followed by oozing from mouth, throat and nose, hematemesis, hemorrhage from bladder and urinary tract. The purpura involved the right leg, and there were pressure points on the posterior surface of body. There were multiple hemorrhages for eleven days. A complicating parotitis seemed to have a marked effect on the hemorrhagic tendency. Medication was unsatisfactory. As a last resort, when other stimulants failed, camphorated oil was given hypodermically in doses of from 15 to 30 drops, as was necessary. Its action was satisfactory.

7 *Office Treatment of Diseases of the Rectum, with a Description of Some New Methods. C. B. Kelsey, New York.
8 *Vapor Method of Anesthesia. J. T. Gwathmey, New York.
9 Etiology and Elimination of Diabetes. G. L. Curtis, New York.
10 *Cost of Modern Hospitals. S. S. Goldwater, New York.

7. **Office Treatment of Diseases of Rectum.**—For securing local anesthesia, Kelsey prefers eucain to cocain, and he also believes that this agent is much to be preferred to the injection of water for the same object on account of the large amount of fluid required in the latter case. Local anesthesia is open to the serious objection, however, that by it the sphincters can not be stretched without pain, on which account a very large proportion of rectal surgery is left dependent on general anesthesia. In speaking of fissure, Kelsey says that, while not the method of choice, still almost as many cures can be effected by incising the sphincter under local anesthesia as by stretching it under gas or ether. The application of the actual cautery for pruritus is, if anything, more satisfactory if done in several sessions under local anesthesia than if but one treatment is given under general anesthesia. Fistula can sometimes be treated satisfactorily in the office, but much judgment is necessary in selecting the cases. Kelsey also describes a new office treatment for hemorrhoids, which he has practiced for some time with good results. It consists in punctate cauterization of the tumors with a needle heated by electricity, the parts being first rendered insensitive by injecting a few drops of weak eucain solution. Only one or two applications are made at a time, and the treatment should not be repeated oftener than twice a week at first. The patient is not expected to be confined to the house or kept from his ordinary business. The time consumed by the treatment in an ordinary case is usually about three months, though it can be done in much less. Kelsey has not observed any complications during ten years' use of the method, and he considers it a valuable procedure in cases in which, on account of the patient's timidity or for other reasons, the clamp and cautery or ligature are not used.

8. **Vapor Method of Anesthesia.**—Gwathmey describes a modification of the Braun and Harcourt inhalers. The apparatus is intended to be used with ether and chloroform administered with or without the admixture of oxygen, but ethyl chlorid or nitrous oxid may also be used in inducing anesthesia. Anesthesia with his inhaler is said to be better than that induced by the drop method, as the concentration of the anesthetic mixture is accurately controllable instead of being dependent on the patient's manner of breathing, and while the gas-ether sequence is the quickest and safest routine method of anesthetizing, it is unphysiologic and will probably be superseded by the vapor method, or some other, in the near future. The advantages claimed for the method, in addition to the exact control of the anesthetic vapor and the ability to change from ether to chloroform instantly at will, are the ease and pleasantness of induction, and the fact that excitement is usually absent or is very slight, the breathing is regular and natural, the lid reflex is never entirely absent, the breathing and pulse are usually normal, the amount of anesthetic used is very small, after-effects are absent in most cases, the technic can be acquired more rapidly than with other methods, and a continual narcosis may be kept up without danger to the patient. The apparatus is illustrated and details of its application under varying conditions, particularly in surgery about the mouth, are given.

10. **Cost of Modern Hospitals.**—Goldwater analyses at length the conditions which cause the cost of the modern hospital building to be so much in excess of what was the case a generation ago. He estimates that a hospital of 1870, of 450 beds with a space allowance of 6,000 cubic feet per patient, could be built to-day at a cost of $1,200 a bed. A modern hospital with the same space allowance would cost double, or $2,400 a bed, while in a hospital recently built 11,000 cubic feet were allowed for each patient, and the cost was approximately $4,400 a bed. The author then analyses at length the various features entering into the construction of the modern hospital which contribute to raise its cost to so great a degree, such as fireproof construction, electric light and power, laundry, kitchen, refrigeration, surgical facilities, disinfecting and sterilizing plants, accommodations for the staff, nurses and employes, laboratories, etc. He summarizes by saying that, aside from economic causes which are beyond our reach, the high prevailing cost of construction is apparently due to new methods of disease classification and treatment, to better nursing, to the discovery of scientific methods of diagnosis, to an application of the principles of hygiene to wards, workrooms and living rooms, to the desire to release from the wards during part of the day convalescents to whom the atmosphere of the sick room is detrimental, and, finally, to the evolution of the fireproof, and to a certain degree germ-proof, building. If we apply to all these improvements the rigid tests of result, we shall find that the test is fairly met; but while we may grant that to build a general hospital embodying all the features enumerated is to tread the path of wisdom, we may nevertheless question the propriety of investing so much capital in the construction of such a plant. The author then proposes the plan of having the hospital maintain in the country a less expensive branch building for the reception of the convalescent patients, and shows that in this way a much larger number of patients can be provided for at the same expense. For example, the sum of $1,000,000 will provide a city hospital for 250 patients, but invested in a city hospital with country annex it will furnish accommodations for 300 patients. The conditions of operating will also be such as to render this the most economical system of managing the hospital, and he urges universal adoption of the plan.

11 Teaching of Failures. F. L. Hupp, Wheeling, W. Va.
12 Symptomatic Treatment of Tuberculosis. J. R. L. Daly, New York.
13 *Four Cases of Cerebrospinal Meningitis Probably Due to the Pneumococcus. R. N. Willson, Philadelphia.
14 *The Gynecologic Bladder. A. E. Gallant, New York.
15 Ideal Dental Narcosis. M. Green, New York.

13. **Cerebrospinal Meningitis Due to Pneumococcus.**—These cases are reported by Willson for two reasons: First, because they demonstrate that the popular teaching to the effect that pneumococcus meningitis is, *a priori*, a fatal condition, is not altogether warranted by clinical evidence; and, second, because from the similarity of the clinical pictures they offer an opportunity of discriminating between this and other forms of cerebrospinal inflammation. A diplococcus representing the pneumococcus was obtained on examination of the cerebrospinal fluid of three of the cases. Two patients also had some pneumonic involvement. In one case no bacteria could be found. In three of the four cases the onset was sudden. In the fourth case the prodromal symptoms extended over the greater portion of a month, consisting mainly of occipital

headache and eventually the symptom-complex of optic neuritis. Cephalalgia was present and intense in every case from the start until delirium or coma set in. Delirium was present early in all the cases, except one in which it appeared after a long prodromal period, and in all it disappeared after drainage of the cerebrospinal canal. The patellar and plantar reflexes were absent in all cases on both sides very early and throughout the course of the disease. The ocular reflexes were almost normal in every case and at all times. Kernig's contracture was present in the hamstring muscles in all the cases. The tendon reflexes of the upper extremity appeared intermittently and irregularly and then were abnormal. The treatment in all the cases was identical and consisted in the prompt withdrawal of all the obtainable cerebrospinal fluid, with the object of relieving intracerebrospinal hypertension. Willson is convinced that this procedure may render mild an otherwise grave condition.

14. **Gynecologic Bladder.**—Of 500 cases seen by Gallant, 213 gave a history of some abnormality or symptom referable to the bladder. Six of these cases occurred in children between 5 and 15 years of age. Gallant is convinced that frequent and painful micturition is met with in about one-third of the females who apply for gynecologic advice. In 25 per cent. this is due to specific gonorrheal urethritis, often associated with vaginitis, etc., although but few cases of gonorrheic infection are met with after the age of 32. Vesical prolapse and intrapelvic or abdominal tumors are the most common factors after 30. Uterine displacement, inflammation involving the broad, the uterosacral ligaments, the tubes and ovaries must be reckoned with and relieved by appropriate measures before the bladder symptoms can be cured. As changes in the urine-producing symptoms do not occur in more than 5 per cent. of all cases, after medical treatment has been tried for a time and found wanting, the pelvis should be explored digitally and the anal region inspected, not infrequently the rectum and sigmoid as well. Whenever urinalysis points to calculi or infection in the bladder, ureter or kidney it is Gallant's custom to pass the cystoscope and to catheterize the ureter.

16 *Diagnosis of Cancer and Ulcer of the Stomach by the Use of Expert Methods of Clinical Procedure. H. F. Hewes, Boston.
17 *Brief Consideration of the Surgical Treatment of Diseases of the Stomach. J. T. Bottomley, Boston.
18 Resection of the Nasal Septum. L. E. White, Boston.

16. **Diagnosis of Cancer and Ulcer of Stomach.**—Hewes details the result of an experimental study of the subject by modern clinical methods of observation with special reference to the indications obtained by the use of those particular methods specially adapted to the study of the stomach, that is, the study in which the value of the indications offered by the clinical findings obtained is proven or tested by the pathologic findings found at the operation or postmortem. In 21 cases of stasis which came to operation or postmortem the cause of the condition was found to be ulcer at the pylorus in 10 cases, cancer at the pylorus in 10 cases, and adhesions about the pylorus in 1 case. Hewes believes that he is justified in saying that the finding of stasis in any case of stomach disorder is in itself a very suggestive point in connection with the possibility of the existence of ulcer or cancer at the pylorus. When this sign is taken in connection with other findings, as the size and location of the stomach, the presence of blood, an anemic condition of the patient, etc., it frequently confirms the diagnosis of cancer or ulcer. Hewes examined the contents of the fasting stomach at least twelve hours after the ingestion of food or material of any kind. The findings in the fasting contents which are indicative of stasis are (1) the presence of an abnormal food residue and (2) the presence of abnormal fermentation in the stomach. Of 160 cases examined for blood, it was found present in none of the chronic cases, except those which were later proved to be cancer or ulcer of the stomach. In 18 cases of stenosis from all causes blood was found in 9.

17. **Surgery of Stomach Diseases.**—Bottomley says that a surgeon should be asked to see a gastric case (1) just as soon as there is even a suspicion of cancer; (2) in a case of supposed acute gastric ulcer just as soon as a reasonably long course of medical treatment has failed to give a very definite improvement, after from five to eight weeks; (3) just as soon as there is doubt in the diagnosis of any gastric case; (4) in all chronic ulcers; (5) in all complications and sequelæ of both acute and chronic gastric ulcers.

25 *Case of Polycythemia and Cyanosis.* A. J. Zimlick, Philadelphia.

22. **Extraperitoneal Rupture of Bladder.**—Eastman reports three cases of extraperitoneal rupture of the urinary bladder complicating fracture of the pelvis, in which the treatment consisted in combatting shock (chiefly with normal salt solution and adrenalin), in the removal of the clot, suture of the rent in the bladder, appropriate bladder drainage, rest, and the application of a bandage in such a manner as to prevent movement of the pieces of bone which were broken off. In the first case cited a large spicula of bone from the right horizontal ramus of the pubis was found thrust through the anterior bladder wall below the peritoneal fold. The second case was one in which the rectum and urinary bladder were transfixed by impalement on some sharp object in a railway wreck. In the third case the anterior wall of the bladder and roof of the prostatic urethra were torn for a distance of two and one-half inches as the result of a crushing injury in the region of the pelvis inflicted by being caught under a falling mass of frozen gravel while at work in a gravel pit.

32. **New Perineorrhaphy.**—Holden denudes a triangular shaped area on the vaginal surface, the apex of the triangle being from 4 to 6 centimeters from the outlet in the median line. From this point the denudation runs out to the lower part of the remains of the hymen, the upper and outer lateral limit being about the same as in the Emmet operation. The external denudation is brought down to a point which is usually just above the position of the sphincter ani. The limits of the denudation are first marked out with the knife, then the vaginal mucosa is removed with the Emmet scissors. The border of the levator ani muscle on one side is now felt by palpation with the finger just behind the ischiopubic ramus. Under the guidance of the palpating finger this broad edge of

muscle is seized with the mouse-tooth dissecting forceps through the overlying fascia and connective tissue and drawn out toward the median line. A round needle bearing a silk suture transfixes the fascia and muscle. The suture is not tied. The ends are clamped, and the suture is used to draw the muscle forward and to make it prominent when later in the operation it is necessary to pass sutures through the muscle. A second suture is next passed through the muscle of the opposite side in a similar manner. The denudation of vaginal mucosa, of course, should extend high enough on the lateral walls of the vagina to allow the muscles to be brought together easily in the median line. Two external sutures of silkworm gut are now introduced, each suture passing through skin and subcutaneous tissue, through the levator ani on the same side, then through the opposite muscle from before backward, and finally out through the skin and subcutaneous tissue on that side. When the needle is passed through the levator ani, an assistant pulls on the silk traction suture which has previously been passed through the muscle, making it stand out, and a deep bite can be taken, passing through the entire muscle. The lowest suture is put near the rectum, the left forefinger of the operator pushing the rectum down so that it is not injured. The second suture is placed about 2 centimeters above the first suture. When these two sutures are drawn tight the borders of the two muscles are closely approximated, as are also the edges of the skin incision. The muscles are also held firmly against the skin and subcutaneous tissue. The silkworm gut sutures are not tied until after the internal stitches are placed and tied. The temporary traction sutures through the muscles may now be removed, if desired, as the muscles are well splinted out and rendered sufficiently prominent by the silkworm-gut sutures. The first internal stitches are of plain catgut and begin at the apex of the triangle. Three or four stitches are usually taken, uniting the cut edges of the mucosa and catching enough of the denuded surface between to prevent leaving any dead space and to stop all bleeding. A figure-of-eight stitch is next placed. Formalin or chromic catgut is used. The stitch starts on the right-hand side and passes through mucosa and underlying tissue to the posterior surface of the muscle. Without touching the muscle of that side it is carried to the opposite side and pierces that muscle from behind forward. It then passes to the anterior surface of the muscle on the first side and passes through that from before backward. Finally, passing to the second side, it is brought out through the mucosa and underlying tissue in the same way as it entered on the first side. Two such stitches are inserted. The first one pierces the muscles between the two silkworm-gut sutures, the second goes through the muscles above the uppermost silkworm-gut stitch. By tying these two figure-of-eight sutures the borders of the levator ani muscles are brought together, the cut edges of the vaginal mucosa are nicely approximated and the mucosa, as a whole, is bound down firmly to the posterior surface of the muscles. By tying the silkworm-gut sutures the anterior part of the muscular perineal wall is covered by skin and subcutaneous tissue, the muscles are still more closely approximated and are firmly bound to their covering of subcutaneous tissue and skin in front. One or two superficial stitches of plain catgut are sometimes necessary to approximate the skin or mucosa at the upper part of the wound. The advantages of the operation are said to be as follows: A thick, firm perineal body is built up, which narrows the outlet. The axis of the outlet is lifted up out of the direction in which the intra-abdominal pressure is transmitted downward in the upper part of the vagina. A vaginal sphincter of the voluntary muscle is incorporated in the perineal body. The muscles are brought together in front of the rectocele. The rectocele is, therefore, pushed back and obliterated, not partially incorporated into the perineal body, as in the Emmet operation. A good cosmetic result is obtained and an even linear scar is left. Holden has used this method in about twenty cases with uniformly good results. The silkworm-gut sutures are removed on the twelfth day.

41. **Mortality in Operations on Fibroids.**—From 1896 to March, 1905, Baldy operated on 248 cases of fibroid tumor of the uterus, with a mortality of 8.4 per cent. In the last 128 patients operated on during the past 39 months, the mortality was 2.3 per cent. The greatest mortality, 9.21 per cent., occurred in 219 cases of supravaginal hysterectomy. Fourteen cases of panhysterectomy had a mortality of 7.14 per cent. Eleven cases of abdominal myomectomy, three cases of vaginal hysterectomy, two cases of vaginal myomectomy and one case of vaginal myomectomy (Downes) gave no mortality.

45 *Acute Pericarditis Complicating Acute Lobar Pneumonia. J. A. Chatard, Baltimore.
46 Rise of the Present Conceptions as to the Cause of the Heart Beat. E. G. Martin, Baltimore.

44. **Unusually Large Aortic Aneurism.**—The case reported by Hough is interesting not only because of the unusual size of the aneurism, but also because of the presence of a collateral venous circulation. The patient, aged 60, occupation baker, gave a history of having exerted himself considerably at times lifting barrels of flour. He never, however, noticed any bad effects from this. Two years ago he began to complain of pain in the chest, which seemed to be worse at night, interfering considerably with his sleep. Later he developed a slight cough and dyspnea, with some harshness of the voice. A swelling developed gradually near the right border of the sternum, between the second and fourth costal cartilages, which finally reached the size of a small lemon. It was pulsating and expansile. There was no pulsation of the vessels of the neck, and no evidence of venous compression nor of irritation of the sympathetic. About a year later there was noticed an enlargement of the superficial veins of the right half of the body. These veins rapidly became more dilated and tortuous, the flow being from above downward. The veins entering into this collateral circulation were, in the order of their size, the right superficial epigastric, a large branch from the left superficial epigastric joining its mate near the umbilicus, several lateral thoracic veins, the right jugular and a network of superficial veins over the tumor and over the superior and anterior surfaces of the right shoulder. This collateral venous circulation was thought to be due to pressure on the right innominate vein and perhaps also slightly on the superior vena cava. One month later well-marked tracheal tugging set in and an area of softening appeared at the summit of the tumor. At no time was there any weeping or leakage of blood. Death ensued two months later, caused by gradual failing in strength and dyspnea.

45. **Acute Pericarditis Complicating Pneumonia.**—Chatard reports on 665 cases of acute lobar pneumonia admitted at the Johns Hopkins Hospital during a period of sixteen years. These figures include all cases, both those admitted with the disease and those developing terminal pneumonias. Acute pericarditis was present in 31 patients, or 4.66 per cent. In 13, or 41.9 per cent., pericarditis was recognized during life. In the remaining 18 patients it was only recognized at autopsy. Autopsies made in 26 instances confirmed the diagnosis of acute pericarditis or showed its presence when not suspected before death. The average age of the patients was 32.5 years. The complication occurred more frequently in young adults, only 5 patients out of the last 19 in this series being above the average age (32.5 years); the majority were much younger. There were 22 males and 9 females. Of the males 10 were white and 12 colored; among the females 5 were white and 4 were colored. The average duration was 6 days. The mortality was extremely high, 29 patients out of the 31 dying, or about 93.5 per cent. A marked history of alcoholism was given by 10 patients. Occupation had little bearing on the disease, the majority being laborers, as in most hospital series. Two patients gave a history of previous attacks of pneumonia. Another had a pneumococcus infection, the organism being cultivated from the blood during life. Four cases were admitted in active delirium and two patients became delirious during the course of the disease—delirium, therefore, occurring in 19.3 per cent. There were two instances of terminal pneumonia, or 6.45 per cent. The pneu-

mococcus was obtained in culture in 16 instances and found microscopically in cover-slip smears made at autopsy 7 times when the cultures were negative, a total of 23 in 29 autopsies. From the pericardium the pneumococcus was cultivated 12 times and the smears showed its presence in 7 other cases. Consequently, in 19 of the 29 cases of pericarditis the pneumococcus was the organism present. No other important organisms were cultivated, in most instances the cultures of smears being sterile or contaminated. The treatment of patients in whom the pericardial rub was recognized during life was of the general supportive character usually employed in pericarditis. Locally ice bags and blistering were tried. All treatment, except in the cases of two patients who recovered, seemed to be unavailing. In no instances was aspiration or free drainage tried. Chatard concluded that pericarditis, developing during the course of an acute lobar pneumonia, is a most serious and important complication, occurring more especially in young adults, frequently insidious, latent, and often not recognized during life. It appears to arise as frequently by a metastatic process as by direct extension. Treatment is very unsatisfactory and often unavailing, except when fluid is present, in which case it is more surgical than medical. In all patients with pneumonia a most careful watch should be kept on the heart, as this complication appears to be much more frequent than is generally supposed, and urgent treatment in the early stages may materially reduce a high mortality.

51 *Bloodless Resection of the Rectum. E. Laplace, Philadelphia.
52 Syphilis Infection and Paretic Dementia. J. G. Kiernan, Chicago.

51. Bloodless Resection of the Rectum.—La Place describes his operation as follows: The patient, under anesthesia, is placed in a recumbent position with the thighs flexed on the abdomen and the pelvis somewhat elevated. The abdomen is brought up to the full extent of the prolapse by means of a volsella forceps and secured in this position by assistants. A curved, large Hagedorn needle, armed with stout twisted silk, is introduced through the double thickness of the rectum on a level with the margin of the anus. The ligature is then cut in half, resulting in two free ligatures, and left in this condition for a moment. About an inch away, on the same level, the needle armed with a similar ligature is introduced through the double thickness of the rectum. A finger introduced within the inner circumference of the rectum will guide the needle; it is brought out and the ligature cut in half as before. One end of the thread from the first ligature is tied to one end of the thread of the second ligature, making a knot within the inner cylinder (caliber) of the rectum. This is then drawn tight to the outside. These two threads are now tied together as tightly on the outside. Thus all the tissues comprised in the double thickness of the rectum between the point of entrance of the first suture and the second suture have been absolutely and completely compressed. There is a free thread left from the second ligature. A third ligature is introduced in the same manner an inch away from the second, and on being cut one of the threads is united within the rectum with the remaining thread from the second ligature, thereby making a continuous thread within the rectum. The two corresponding ends are now tied tightly on the outside, compressing all the tissues of the rectum between suture No. 2 and suture No. 3; and thus sufficient sutures are placed circularly around the rectum on a level with the margin of the anus until the last ligature is introduced. Supposing seven ligatures to have been thus introduced, there is one free thread left from ligature No. 1 and this is tied to the free end of the last inserted suture within the cut. In this way all the tissues of the double thickness of the rectum beyond the margin of the anus have been effectively compressed and ligated. An amputation knife is then used to remove bodily and at once all the rectal tissues below the ligatures. There is almost complete absence of hemorrhage. In order to suture the margin of the anus with the cut extremity of the rectum, each ligature, beginning with No. 1, is removed singly. This gives an area about one inch in length to be dealt with for arrest of hemorrhage and for suturing the cut extremities together. On removing the ligature any hemorrhage which takes place is controlled by forceps and a silk ligature applied. Suturing the parts is accomplished by through-and-through continuous suturing with chromicized catgut. As many sutures are placed as are necessary for solid union of the parts; and when the distance between the first and second ligature has been closed the second ligature is cut away. Having arrested the hemorrhage by the same method, suturing is done as before. This method is carried on until the whole circumference of the gut has been reunited. It is possible thus to resect as much as eight inches of the rectum with very little hemorrhage and with great facility. Further treatment is practically *nil.* The patient is put on a liquid diet, and an enema administered daily keeps the parts clean. The catgut drops away in time and no complications are likely to set in. The procedure is also free from postoperative pain.

53 *Stenosis of the Cervix Uteri. A. H. Goelet, New York.
54 Tuberculosis of the Shoulder Joint, with Radical Operation for Its Removal. W. L. Allison, San Antonio, Texas..
55 Present Treatment of Fractures of the Forearm. J. E. King, Richmond, Ind.

53. Stenosis of Cervix Uteri.—Goelet considers the two-branch dilator an ideal instrument inasmuch as the required dilatation may be accomplished gradually and without injury if ordinary care is observed and it is not permitted to slip out. The degree of dilatation should be only sufficient to permit the easy accomplishment of the work to follow. Goelet finds very much less necessity for employing the steel dilator in these cases now than formerly, and believes it is only necessary in the very few cases that do not yield to negative electrolysis, employed intelligently to accomplish a certain purpose, and not haphazard. Some method of dilatation, however, is essential when curettage is necessary or when the uterine stem is to be inserted. Forcible dilatation, he says, serves only to expand the caliber of the canal temporarily, and unless the condition that produces the constriction is done away with recontraction is certain to follow sooner or later. The result obtained with negative electrolysis is more certainly permanent if it is employed properly, because it stimulates an altered circulation and nutrition, softens indurated tissue and effects drainage of the cervical gland as well as drainage from the uterine cavity. With it the cervical canal can be rendered more certainly and permanently patulous than by any other means; on the other hand, it is capable of doing an infinite amount of harm if it is used improperly. For removal of granulations at the internal os and in the canal the sharp curette must be used after dilatation with the steel dilator, and a patulous condition of the canal must be maintained thereafter by appropriate treatment until a normal condition has been restored. On removal of the granulations with the curette Goelet makes an application of pure carbolic acid to that location only and does not carry it up into the cavity of the uterus. Subsequently, beginning a week after removing the granulations, applications of negative electrolysis are made to the canal by means of conical electrodes, selecting the size that may be inserted without any force. These applications are made at first every second or third day, and later at gradually increasing intervals until the cervical stricture is softened and the canal remains normally patulous. Care is observed never to use the current long enough each time or strong enough to produce cauterization; therefore, never more than a 10-mp. current is used for more than three minutes. Under these applications the mucous membrane heals without contraction and the canal will remain patulous. The same method of negative electrolysis is applicable when the stenosis is due to diseased and occluded glands, and it may be preceded or not by dilatation with the steel dilator, as may be required. It is also effective in all simple uncomplicated cases of stenosis due to chronic inflammation with thickening of the mucous membrane, or simple congestion with edema, and for the conical elongated cervix and undeveloped uterus. *Goelet limits the* application of the intrauterine stem to those cases of stenosis due to or associated with hyperplasia and induration of the cervical structure and for flexions. It is never kept in the uterus, however, for a longer period than a week, and during that time the patient is confined to bed. This stem is made of glass tubing, open at each end to permit free drainage, and it is retained in position by loose packing of gauze in the vagina. It is removed repeatedly during this time, cleansed and replaced. Subsequently the applications of negative electrolysis will be necessary in some cases to supplement the action of the stem in restoring a normal condition of the uterine wall, for that is its purpose. Its presence in the canal stimulates an altered circulation and nutrition, and consequently alters the condition of the cervical structures. Within a few days after it is introduced the whole cervix becomes noticeably softened, and the caliber of the canal is so much enlarged that it is difficult to retain the stem in position, though it was at first grasped firmly by the constriction of the cervix.

58. **Bacteria Encountered in Suppurations.**—Bergey examined thirty pus cases, including 6 that were diagnosed as tuberculous; 4 were abscesses of the inguinal and rectal region; 2 were cases of empyema; 1, carcinoma of the breast; several were superficial ulcers, and the remainder were either suppurating wounds or cases in which suppuration followed various operative procedures. In 24 of the 30 cases staphylococci were encountered either alone or in conjunction with other organisms. Streptococci were found six times. *Bacillus pyocyaneus* was found in 9 cases. In 4 of the cases *Bacillus coli* was encountered. Aside from these organisms, *Bacillus proteus vulgaris* was encountered once, and several bacilli the exact identity of which was not definitely determined. In 13 of the cases an organism having morphologic characters simulating those of *Bacillus diphtheriæ* was encountered. *Bacillus pseudodiphtheriticum* was found in 13 cases, or 43.3 per cent. of the cases examined. In many of the specimens of pus *Bacillus pseudodiphtheriticum* was present in very large numbers, far exceeding in number all the other bacteria. The results of Bergey's investigations indicate that, aside from the usually recognized pyogenic organisms—namely, the staphylococci, streptococci and *Pseudomonas aëruginosa*—a very large proportion of suppurations contain, in addition to one or more of these organisms, *Bacillus pseudodiphtheriticum*. The experiments and observations made thus far with *Bacillus pseudodiphtheriticum* indicate that it has distinct, though rather mild, pyogenic properties. The results of the investigation indicate that it is capable of producing a soluble toxin, but, on the other hand, like the staphylococci and streptococci, it produces an endotoxin.

60. **Lessons to be Learned from the Yellow Fever Epidemic.**—Baxter states that he is convinced that, as a result of the present epidemic of yellow fever, uniformity of quarantine regulations will result, but not till all matters relating to public health and quarantine are relegated by the states to the general government, which alone can act with fairness and justice to all. To attain this he urges physicians to advocate such a course in all communities in the South. He states that this is the most important question which confronts the South to-day in view of the closer communication which will be had with South American ports in the near future. Another lesson which has been taught by the present epidemic is the necessity of municipal cleanliness in regard to malaria as well as yellow fever.

65 *Results of Decapsulation of the Kidneys for Nephritis in Children. E. E. Graham, Philadelphia.

65. **Decapsulation of Kidneys for Nephritis in Children.**—The histories of ten recorded cases are reviewed by Graham and one personal case is added. Graham found that a careful study of the patients operated on shows that if the nephritis is of comparatively recent origin, the urinary evidences of the nephritis being perhaps only of some months' duration, and if under the best medical care the patient is not improving, but is growing progressively worse, and there is more or less renal insufficiency, a rapid improvement may follow a decapsulation. In Graham's series of 11 cases there were 5 deaths, or 45.4 per cent. Of these five deaths, one patient lived in a much improved condition for a year and died from an attack of acute nephritis. One was distinctly improved by operation. There were four probable, or at least possible, complete cures, or 36.3 per cent. Two patients were not improved. Graham believes that all the patients would probably have died if not operated on. The forms of nephritis most benefited by operation are the acute and subacute cases, but only those patients should be operated on who are not doing well under appropriate medical treatment. The results in the chronic cases are not favorable. Regeneration of the kidney tissue in the child is more likely to occur, and the kidney lesions in the child are less likely to be complicated by degenerations in other portions of the body, and, hence, improvement possible in the first few months following decapsulation is more apt to be permanent in the child. The eye-ground changes are less significant in the child than in the adult.

84. **The Infamy of Patent Medicines.**—Erkiletian states that there is an independent moral duty in the life of a physician which obliges him to uphold the honor and dignity of the profession, to enrich the resources of his knowledge, to be loyal to the laws of his conscience, his country and his God, and to

equip himself against prevailing evils. He considers the patent medicine evil a menace to our civilization. He declares that no reputable physician will ever prescribe a patent medicine or support its cause, and that there exists no evil which needs to be more seriously considered by the advocates of clean scientific medicine than this one of patent medicines. He calls attention to the fact that more harm has been done to the medical profession through the activities of the patent and proprietary medicine manufacturers than by any other means. Erkiletian criticises some widely advertised remedies and calls on every physician to aid in the fight against them. He advises educating the public in regard to patent medicines and appealing to the legislature for more stringent laws. He also advocates a higher standard of education for the physician, thus eliminating those who through ignorance of the action of drugs prescribe proprietary remedies.

September 30.

1 *Surgical Treatment of the Non-malignant Diseases of the Stomach. B. G. A. Moynihan, R. Saundby, H. Hartmann, J. M. T. Finney, C. M. Moullin, F. Eve, and others.
2 *Further Experiments on the Sterilization of the Hands and the Skin. C. L. Green.
3 Congenital Dislocation of the Hip Joint and Its Modern Treatment. J. J. Clarke.
4 *Sterilization of the Hands. C. Y. Pearson.
5 Spontaneous Gangrenous Formations in the Vermiform Appendix. J. D. Malcolm.
6 Surgical Treatment of Chronic Gastric Ulcer and Gastric Dilatation by the Operation of Gastrojejunostomy and Jejunojejunostomy. T. G. Atkins.
7 Surgical Treatment of Malignant Disease of the Rectum. C. Ball, F. S. Edwards, H. Hartmann, E. S. Bishop, T. G. Atkins, S. White and others.
8 Unusual Condition of the Large Intestine Associated with Carcinoma in Two Sisters, Together with Carcinoma in a Third Sister. C. P. Childe.
9 Case of Gangrenous Appendicitis. T. G. Atkins.
10 Cystic Tumor of Omentum. L. A. Bidwell.
11 Acute Osteomyelitis and Periostitis of the Spine. A. H. Tubby.
12 *Two Cases of Operation Involving the Thoracic Duct. R. Bucknall.

1. **Non-malignant Disease of Stomach.**—Hartmann has performed 119 operations for non-malignant diseases of the stomach. Among these were 4 for perforated ulcers, 5 pylorectomies, 1 excision of the lesser curvature, 2 gastroplications and gastropexies combined, 1 gastroplasty, 1 pyloroplasty, 1 duodenostomy, 1 gastrolysis, and 1 section of kink of the pylorus. The operation which Hartmann generally considers the best in the treatment of the non-malignant diseases of the stomach is gastroenterostomy, an operation which he has performed 102 times. These 102 cases are divided into three series. The first series embraced 21 cases, with a mortality of 23.7 per cent. The second series consisted of 34 cases, with a mortality of 8.8 per cent. In the third series there were 47 cases, with a mortality of 6.3 per cent. The operation resembles, in many respects, that of Mayo Robson and Moynihan. It is a posterior gastroenterostomy. Hartmann does not use clamps. The patient is placed in a slight degree of the Trendelenburg posture so that the contents of the stomach are in the cardiac part, and if the patient is well anesthetized nothing escapes when the stomach is opened. Hartmann leaves about 8 or 9 cm. between the duodeno-jejunal flexure and the anastomosis so that the gut descends in a straight line from the flexure to the posterior wall of the stomach. The sutures are made with silk. The inner one embraces all the coats. It closes the cavi-

ties and is hemostatic. The outer one includes the serous and muscular coats. A long fixation is made of the intestine, going obliquely downward and to the right. The stomach and bowel are opened at the level of the inferior right part of the apposed portion. Hartmann observed the vicious circle only once, in a case in which the stomach was not fixed satisfactorily at the opening in the mesocolon, which lead to an ascent of the intestinal loop through the opening. He found that in case of pyloric stenosis and in moderate hemorrhage recurring many times the patients are cured by gastroenterostomy. The remote results are also good in intractable ulcer not cured by medical treatment and in patients who suffer from hyperacidity. A tonic dilatation with gastroptosis is rarely an indication for surgical interference. In pyloric stenosis, the operative treatment is indicated as soon as the diagnosis is made. In chronic ulcer, surgical treatment is indicated only in the case of an ulcer with mechanical troubles and in those of an ulcer which gives the pyloric syndrome. In cases of excessive hematemesis, Hartmann operates only when there is distension or peristaltic contraction of the stomach, and then he does only a gastroenterostomy.

2. **Sterilization of Hands and Skin.**—Green carried on a series of experiments to determine the relative value of aqueous and alcoholic solutions of sterilizing agents used for the purpose of sterilizing the skin of the patient. Experiments with aqueous solutions of all the antiseptics in common use, even those of the greatest strength that could be tolerated, proved that far from rendering the skin more sterile they had rather the opposite effect. Not only did the compress fail to destroy the micro-organisms situated on the skin, but it loosened the surface epithelium, rendering it easily detachable under the surgeon's manipulations. On the other hand, Green found a decided advantage in the prolongation of the action of the spirituous antiseptics. A greater proportion of the tests made proved sterile, and in no case was there any marked infection. He is convinced that alcoholic compresses readily and materially reduce the infectivity of the skin to a degree which at present is not possible to attain when treating the hands.

4. **Sterilization of Hands.**—Pearson describes his method as follows: For hands not already prepared for sterilization, a preparatory process has to be gone through, which consists of careful trimming of the nails, washing with ordinary soap and hot water, then, if the skin is at all rough, they are well rubbed with sterile sea sand so as to render the skin smooth and to remove redundant epithelium. This preparatory process is not necessary in the case of those whose hands are already in good cosmetic condition. The only form of nail cleaner employed is a piece of sterilized orange wood. The disinfection is divided into three stages: 1. Washing for five minutes with spirit of green soap and very hot water. The scrubbing is done under a tap of running water, and two sterile nail brushes are used in succession. 2. Dehydration by carefully rubbing the hands and forearms with pieces of gauze soaked in methylated spirit; this occupies three minutes. 3. Disinfection proper by rubbing for two minutes with gauze soaked in a 1 to 500 solution of mercuric biniodid in 70 per cent. alcohol. The biniodid is washed off with methylated spirit; the hands are then washed in normal saline solution. Out of the 18 cultural experiments made from normal hands treated as above, absolute sterility was obtained in 8, and practical sterility was obtained in all the experiments, the greatest number of colonies in any one experiment being 10. Out of the 12 experiments conducted on hands infected with highly resisting organisms, such as the spore-bearing hay bacillus, practical sterility was attained in 9, absolute sterility in 1; in 2 there was moderate infection. Pearson has met with only one person whose hands were irritated by this method.

12. **Operations Involving the Thoracic Duct.**—In the first case reported by Bucknall the thoracic duct was accidentally torn open during an operation for the removal of some tuberculous glands from the root of the neck in a man aged 54. The wound of the duct was not recognized at the time of operation, but twenty-four hours later there was a copious flow of lymph and chyle from the wound, and the patient lost strength and weight in a remarkable manner. Plugging having proved ineffectual, the torn ends of the duct were exposed and ligatured on the sixth day. No more fluid escaped, and with the reabsorption of chyle the patient rapidly recovered his strength and gained in weight. Two months later, however, he suddenly developed signs of widespread general tuberculosis, and rapidly died of this malady. In the second case the convexity of the thoracic duct in the root of the neck was caught up in some malignant glands in the posterior triangle, secondary to a cancer of the breast, which had previously been removed. The lumen of the part of the duct involved was entirely obliterated; it was, therefore, removed with the glands and its free ends were ligatured, without giving rise to any definite symptoms afterward.

The Lancet, London.

September 30.

13 Circulatory and Anatomic Abnormalities of an Acardiac Fetus of Rare Form. M. Campbell and H. D. Shepherd.
14 *Observations on Twenty-six Consecutive Cases of Gastroenterostomy. A. R. Anderson.
15 Empyema in the Posterior Ethmoidal Labyrinth with Paralysis of the Conjugate Movements of the Eyes and Bitemporal Limitation of the Visual Fields. W. Glegg and P. J. Hay.
16 Notification of Pulmonary Tuberculosis in Blackburn. A. Greenwood.
17 Complete Extirpation of the Penis for Epithelioma in a Hawaiian, aged 28 years; Recovery. E. H. Armitage.
18 Two Interesting Cases of Imbecility with Epilepsy. R. G. White.
19 Difficulties and Dangers of the Mastoid Operation, the Vicissitudes of Convalescence, and the Ultimate Result to the Patient. C. A. Ballance.
20 *Case of Mitral Incompetency and Ascites Treated with Apocynum Cannabinum. A. J. B. Duprey.
21 Influence of Nasal Obstruction on the Form of the Face. W. B. Parsons.
22 *Sanatoriums for the Poor and the Eradication of Consumption. R. C. Macfie.
23 *The Occurrence of a Spirillum in the Blood of Patients Suffering from Secondary Syphilis. G. M. O. Richards and L. Hunt.
24 Secondary Effects on the System which May Be Produced by Chronic Enlargement of the Tonsils. H. B. Gardner.
25 Essential Conditions of Steam Disinfection. W. Defries.

14. **Gastroenterostomy.**—Anderson reports on 26 consecutive cases of gastroenterostomy. The operation was performed for recent ulcer in one case, chronic ulcer in 11 cases, pyloric stenosis in 8 cases, and cancer in 6 cases. Three of the patients died, a mortality of 11.6 per cent. In one of these fatal cases the patient had a carcinomatous ulcer at the pylorus which involved the stomach wall and head of the pancreas. The patient lived eleven days after the operation. The second case was one of large chronic ulcer at the pylorus, with stenosis. The patient died from bronchopneumonia and cardiac failure. The third case was one of chronic ulcer on the anterior wall. The patient died on the eleventh day from chronic obstruction and debility. All the carcinoma cases terminated fatally. In the case of 5 of these patients temporary relief was afforded by the operation.

20. **Mitral Incompetency and Ascites Treated with Apocynum Cannabinum.**—The ascites in Duprey's patient developed so rapidly that the man had to be tapped once every four to six weeks. Finally he was placed on tincture of apocynum cannabinum, the dose being gradually increased from 1 to 10 minims, three times a day, with the result that from a very small quantity of concentrated urine, about half a pint, the daily excretion rose to several pints, and whereas tapping before using the drug was urgently needed every month or six weeks, the patient went along for six months without being tapped, and the probability is that if he had not stopped using the drug the fluid would not have reaccumulated.

22. **Sanatoriums for the Poor.**—Macfie discusses the question whether sanatoriums, as at present conducted, are the best offensive and defensive measures against consumption. He is of the opinion that sanatoriums under the present conditions involve a terrible waste of lives and money and, although with conjoint colonies and competent administration they might be made most useful weapons against consumption, yet they must not be permitted to divert philanthropic energy from more profitable and proven measures. Consumption will be most speedily and economically abolished, not by means [illegible]e sanatoriums, but by hygienic improvements, better food, [illegible]ter housing, more open spaces, etc., and by direct mea[illegible]s.

against the disease, along with notification, isolation, disinfection, and house-to-house visitation. An effort to make a few foul, infectious houses clean and airy and sunny will do more to eradicate consumption than can be wrought by many costly colossal sanatoriums.

23. **Spirillum in Blood of Syphilitics.**—Richards and Hunt examined films from every case of venereal sore seen by them and in some they succeeded in finding the organism described by Schaudinn and Hoffman. It appeared to occur in three forms, probably involution forms of the same organism, differing only in thickness, length and the number of spirals; one form being thick and straight or slightly curved, a second of the same thickness as the first but with spirals, and the third one exceedingly thin, distinctly spiral, with a large number of turns and very long. The first two varieties appeared to exist in the secretion and the superficial part of the sore, while the third variety only occurred in the deep scrapings, and in a film from such scrapings the organism could be seen lying among the blood cells. As the secondary stage of syphilis appears clinically to be a stage in which the infection is blood borne, and drawing an analogy from the rose spots of typhoid fever in which bacilli have been found, they took a case of secondary syphilis with a rash of a few days' duration, pricked a typical spot and made the blood films, taking the greatest care to avoid contamination by cleaning the skin with soap and then spirit and using specially clean slides. The films were then stained for five minutes by Giemsa's stain diluted 1 in 3 with distilled water, and on examination were found to contain a spirillum exactly like the fine form found in a sore. Other cases were taken and they have now observed the same organism in three patients. Films were taken from spots on the abdomen, chest and arm. The spirilla do not occur in large numbers and often require a long search and in some of the films only one has been seen. In one patient the organism was seen in a blood film taken on each of ten successive days and in the three cases in which the organism was found in the blood it had previously been seen in all forms in the primary lesion. Richards and Hunt consider the presence of the spirochete in the venereal sore as diagnostic of syphilis.

41 Les kystes de la face fetale du placenta. Plauchu.

26. **Extramedian Symphyseotomy.**—Van Cauvenberghe has been conducting research at Leopold's clinic to determine the practicability of Gigli's method of enlarging the pelvis by sawing the pubic bone aside from the median line. He experimented on cadavers and gives seventeen tables showing the various diameters when the cut edges were separated to different distances. The bladder and the urethra retain their

the median line, and for this as well as for

operation is far simpler and less serious

. He saws the bone *on the side* where

will present after version, except in case

or other obstacle on this side. When the

rated by 3 cm., the true conjugate diameter gains 1 cm., the transverse diameter gains 1.4, and the oblique diameters 1.3 cm. Separation to a distance of 4 cm. does not entail laceration of the capsule of the articulation, but this is liable to occur if the parts are separated to 6 cm., although in some of his experiences there was no laceration even when the distance between the cut edges was 8 cm. Laceration is not a very serious occurrence, but it is better to avoid it. In regard to the limits of the contracted pelvis Leopold has thus delivered a woman with a true conjugate diameter of only 7 cm., the child weighing 3,820 gm. The children are more apt to be small in case of primiparæ, and he has frequently had women spontaneously delivered with a true conjugate diameter of only about 7.5 cm. The limit for symphyseotomy is generally accepted as 7 cm., but van Cauvenberghe is convinced that this limit can be lowered for pubiotomy to 6.75 or even 6.5 cm.

27. **Necessity for Medical Supervision in Breast Nursing.**—Quillier quotes Budin to the effect that the raising of an infant is a science and a very delicate one. The most devoted and enlightened mother love can not supplant the necessity for this science, and only the trained physician is its exponent. The general notion that breast nursing does not require the same supervision as artificial feeding is an erroneous one. The breast may be given too often, too long, or the milk may be deficient in quantity or quality. Quillier gives a number of curves and tables to show the benefit derived from medical supervision of breastfed infants, avoiding disturbances and arresting incipient troubles, and aiding the child to develop into unusual health and strength.

34. **Nasopharyngeal Infections in Young Infants.**—The prognosis is always more or less grave, and every effort should be made to prevent infection of the nose and pharynx in the new born. Veillard advocates disinfection after birth of the nasopharyngeal cavities the same as of the eyes. Laurens admits the advisability of this, but—on account of the anatomy of the parts at this age—warns against the air douche or introduction of any fluid; dry gauze or cotton alone should be used. Another suggestion that has been made is not to allow children with coryza to remain lying down all the time. The Eustachian tube slopes so that mucopus is liable to find its way into the middle ear when the child lies on its back. If paracentesis is necessary, he rinses out the cavity with oxygenated water, first instilling a few drops of liquid vaselin. Certain patients may require more energetic surgical measures. If the trouble is due to the streptococcus alone, an antiserum might be used to advantage in the general treatment, but the infection is generally mixed. The conformation of the nasopharynx in the new born seems to invite infection and to render its treatment difficult. A rhinitis may lead to infectious processes in the eyes, digestive tract, lungs, sinuses or pharynx, or to epidemic cerebrospinal meningitis. Fluids introduced into the nose to rinse it out are liable to make their way into the middle ear or into the bronchi, and thus to carry infectious material to sound regions. For this reason the use of fluids has been entirely abandoned for the purpose by Budin and Brindeau. Intubation of the nose is also dangerous as it is liable to injure the mucosa. The nose can readily be cleared out by instilling some emollient, and when the obstruction has thus been removed, Laurens then instills four times a day four or five drops of neutral oxygenated water (12 volumes), diluted with boiled water to from one to five times its volume. The face should be kept clean of infectious material, especially around the eyes, and the child's head should be slightly raised so that the secretions will have less tendency to run into the pharynx and tubes. Another valuable adjuvant is the instillation into each nostril, five minutes before the child is given the breast or bottle, three or four drops of a 1 to 10,000 solution of adrenalin hydrochlorid. By inducing vasoconstriction in the mucosa this will temporarily restore the permeability of the nose. If this fails the child will have to be fed with a spoon.

35 and 36. **"Infant Consultations."**—The Journal has frequently referred to the out-department of the Paris maternities, in which the healthy children are brought back week after week for medical inspection and advice, a combination of dispensary, baby show, mothers' club and lecture on hygiene. The influence of these "consultations" on the average growth and development of the children has surpassed all expectations. Budin here reports the results in his personal experience, and Mocquot in the "consultations" he has established in six country communities.

37. **Mammary Affections and Breast Nursing.**—Jeannin tabulates the cases observed at the Tarnier clinic in the last four years, and their effect on the mammary functions. The proportion of morbid processes in the breasts was about 10.2 per cent. of the 5,746 women who were able to nurse their children. The majority were observed in the spring. They coincided with uterine infection in from 10 to 22.6 per cent. of the cases in the various years. Breast nursing was apparently normal in 87.5 per cent. of the women who had had but a single attack of lymphangitis; in 57 per cent. of those with recurring lymphangitis; in 68.7 per cent. of those with galactophoritis, and in 40 per cent. of those with mammary abscess.

40. **Sea Water for Subcutaneous Injections in Debility.**—Macé and Quinton report that experiences with 40 weakly children have shown that subcutaneous injection of sea water has a decidedly favorable effect in raising the general tone.

54 *Le rectum bilharzien. M. Letulle.

42. **Small Hemorrhagic Cysts in Ovary.**—Daniel remarks that cysts of this kind occur more often than is generally supposed, and that they show no tendency to spontaneous retrogression. He gives the history in full of fifteen cases he has found in the literature, including Boldt's case of peritonitis from rupture of a hematoma of the ovary. Treatment can only be surgical.

43. **Pneumococcus Peritonitis.**—A case of circumscribed and another of diffuse peritonitis are described, both due to the action of the pneumococcus. The diffuse form was observed in 29 out of the 74 cases of pneumococcus peritonitis on record, and in 16 of these the peritonitis was secondary. The only treatment for the circumscribed variety is early extensive incision with ample drainage. This primary, isolated form is the most common, especially in children. The sudden, high temperature, palpation of an encysted effusion, and diarrhea are its main features. The primary diffuse form presents a syndrome exactly like that of appendicitic peritonitis. The only chance of recovery is by early operation, but the results are less promising than with the encysted variety. The secondary form is generally masked by the primary affection, and differentiation is difficult, but prompt surgical intervention offers the only chance for saving the patient. Some individuals have recovered after an operation in secondary encysted peritonitis, but no case is on record as yet of recovery after operation in the secondary diffuse form.

44. **Tardy Stenosis After Incarceration of Hernia.**—The only treatment is removal of the constricted portion, but greater attention should be paid to prophylaxis of such conditions. Cotte preaches the necessity for abstaining—on principle—from all attempts at taxis, except possibly at the very beginning of the incarceration. If the incarceration has lasted several hours no attempt should be made to reduce the hernia for fear of injury to the intestine with consequent tardy stenosis. If part of the intestine is to be resected, the gut should be removed to far beyond the strangulated portion. In 23 cases treated by surgical measures, the mortality was considerably less than after laparotomies for intestinal occlusion, and the patients rapidly recuperated.

46. **Sarcoma of the Body of the Uterus.**—Piquand's extensive monograph reviews the history of uterine sarcomata. He has collected 416 cases of sarcoma in the body of the uterus, and relates the details of 7 cases of circumscribed sarcoma of the uterine parenchyma personally observed, and of an eighth case showing giant cells, and a ninth exhibiting a sarcomatous polyp. Metastases, he states, are usually located in the lungs or peritoneum, the bladder having been involved in only one case, the intestine in 6 and the lymphatic ganglia in 7.

47. **Cysts in the Mesentery in Children.**—Broca could find only 22 cases in the literature, but has encountered 2 in his own experience. In one the cyst was included in a hernial sac; the patient was a boy of 4. The empty pocket was 15 cm. long, 8 cm. wide at the upper end and 4 cm. at the tip, enclosed in the inguinal hernia. The child recovered rapidly after the operation. Morton published the report of a somewhat similar case in 1896, but the patient was a young man. Broca's second patient was a girl of 6, healthy until four months previously, when violent colic and vomiting occurred and recurred at varying intervals. Symptoms of peritonitis finally developed, the presumptive diagnosis being tuberculous peritonitis with an encysted pocket, as a fluctuating tumor could be palpated in the right side below the umbilicus. There was no fever, but the pulse was 130, the eyes were sunken and bilious vomiting was frequent. The laparotomy revealed a large multilocular cyst in the mesentery, with smaller cysts around it. The large cyst was removed, but the child succumbed the next day. Two small cysts were found on the other side of the mesentery, extending into and through the muscle and mucosa of the intestine. The mucosa was very thin in one of the cysts and had perforated in the other, and this had been the unrecognized cause of the terminal peritoneal septicemia.

48. **Surgery of the Cardia.**—Sencert's illustrated anatomic and experimental study of the surgery of the cardia concludes with a recommendation of esophago-gastrostomy for stricture in this region. He has successfully resected the cardia in living dogs and worked out the technic on the cadaver, as he describes in detail.

49. **Tuberculosis of Kidneys.**—Pauchet publishes the details of a case of primary hematogenic tuberculosis of the kidney cured by nephrectomy eight years ago. He discusses the diagnosis. Nine times out of ten the bacillus arriving by way of the blood infects the cortical zone of one kidney alone. This infection causes hematuria and cystalgia during the first stage, which is essentially chronic, but curable by removal of the focus. The diagnosis should be made before the syndrome is completed by pyuria, bacilluria, pains and enlargement of the kidney. The patient first applies for relief from the cystalgia, as a rule. Urination is painful, and desire to urinate abnormally frequent. No tumor nor ulceration can be seen with the cystoscope, but the mouth of one ureter is congested and swollen. The hematuria is spontaneous, not following fatigue or walking, and may come on at night. It lasts for several days, stopping as abruptly as it began, and is seldom so severe as to affect the general health. The hematuria may or may not be accompanied by ureter colic. The blood is mixed thoroughly with the urine, or it may appear in the form of worm-like clots, from 10 to 15 cm. long. Painless, profuse, spontaneous, hematuria, with the features of renal hematuria, occurring in a young patient should always suggest primary tuberculosis of the kidney. At a later stage the lower end of the kidney will be found abnormally low or enlarged. Tuberculosis of one kidney does not affect the general health in the early phases. When the kidney has been exposed an exploratory incision will decide whether the trouble is due to calculi, cancer or tuberculosis. The entire organ should be removed in case of the latter, resisting the temptation to do a partial nephrectomy. The microscope will reveal tuberculous follicles in the apparently sound parts.

50. Sarcoma of the Cervix.—Piquand summarizes 29 cases of hydatidiform sarcoma of the cervix from Weber's, published in 1867, to Williamson's, published last March. He has further collected 41 cases of other varieties of sarcomata of the cervix, and devotes considerable space to a discussion of the histogenesis of sarcomata of the uterus in general. (See 46 above.)

51. Treatment of Typhoid Perforation.—Domela insists on the fact that the deaths which have occurred after suture of a typhoid perforation have always been the result of another perforation above or below. The sutured perforation has always been found well healed. The danger of these successive perforations should emphasize the necessity for more radical measures than merely suturing the perforation found at the laparotomy. He proposes that the entire diseased portion of the intestine should be excluded from the balance of the digestive tract, and be allowed to recuperate in peace. He suggests total, unilateral exclusion by an anastomosis between a loop of the intestine above and another below the usual site of the typhoid ulcerations. When the abdomen is opened to suture the perforation, the operation would not be rendered much more serious by an ileocolostomy, while the grave prognosis of typhoid perforation amply justifies any measure that brightens the outlook. If perforations occur afterward in the excluded portion of the gut, there is every reason to believe that they would be comparatively harmless in the empty, resting bowel, and would heal spontaneously in time. He concludes with a discussion of the technic.

53. Treatment of Chronic Invagination.—Delore reports 3 cases of chronic invagination treated by operative measures. In the first case he resected the whole invaginated portion and the patient succumbed to the effects of this too radical procedure. In the other cases he resected merely the inner part, drawing it out through an incision in the outer part of the sheath. Both of these patients promptly recovered. The lesser gravity of the latter technic commends it; the results are the same as from total resection. It is described in the text-books as the Maunsell or König method. In 2 of Delore's cases the invagination had been caused by a small tumor which was found in the tip of the invaginated resected part.

54. Bilharzia Rectum.—Letulle observes that "of all the chronic ulcerating affections of the intestine, bilharziosis is most liable to be erroneously diagnosed; and yet its differentiation is extremely easy and as certain as it is elegant." The rectum presents a cylindrical induration of its walls, with numerous ulcerations and adenomata scattered over the non-ulcerated portions. The ulcerations never extend beyond the muscularis mucosæ, while all the elements of the mucosa display a tendency to hypertrophy. The chronic inflammation is generally restricted to the pelvic portion of the large intestine. The resulting rectitis causes so much pain and cachexia that surgical intervention should be considered.

55. Placentation in Hypoplastic Uteri.—The conditions in a hypoplastic uterus are not favorable for normal placentation. After expulsion of the fetus there is liable to be retention of parts of the membranes, entailing amenorrhea for months and absence of the mammary secretion and involution of the uterus. Treatment should be the cautious curettement of the upper necrotic layer of the mucosa. This cures amenorrhea from this cause. Intrauterine treatment should also be instituted to promote hyperemia afterward, such as tamponing with iodoform gauze for several days. Curettement is contraindicated in all other cases of hypoplasia of the uterus, puerperal or postpuerperal, as the mucosa is liable to become regenerated and transformed, improving conditions for subsequent pregnancies. The histologic findings in 5 cases are shown in colored plates.

61. Prevention of Dilatation of External Os.—*Bardeleben* describes 5 cases of what is generally known as conglutination of the external orifice of the uterus. He prefers the term "prevention of dilatation of external os uteri." The cause may be stenosis and rigidity in elderly primiparæ, or it may be due to cicatricial strictures or adherence of the lower pole of the ovum or to overfilling of the amnion, each presenting different indications for treatment.

64. Tracheoscopy in Case of Goiter.—Wild has had opportunity to examine the trachea through the tracheoscope in 1,000 cases of goiter and describes the various findings. His article of 110 pages is illustrated.

65. Defenses Against Bacterial Peritonitis.—The conclusions of Peiser's clinical observation and experimental research are to the effect that after the peritoneum has become infected its power of absorption becomes temporarily diminished. This, he thinks, is evidently a defensive reaction on the part of the organism against threatening septicemia and general intoxication from absorption of the bacteria and their toxins in the peritoneum. The essential struggle against the bacteria takes place in the peritoneum, and the latter must conquer in the struggle or the general organism is doomed. The idea that absorption by the peritoneum is one of the means of defense against bacterial peritonitis and that delayed absorption favors it is erroneous, he thinks, and exactly the reverse he believes is true. He also found that injection of adrenalin into the abdominal cavity retarded absorption by the peritoneum. Exner has recently made the same discovery in regard to absorption of poisons in the stomach. He discovered that an intraperitoneal injection of adrenalin retarded the absorption of ingested poisons. Peiser adds that encapsulation, adhesions and fibrin deposits are only further efforts on the part of the organism to prevent absorption by the peritoneum in case of bacterial invasion. He is convinced that his experimental findings apply also to man to a certain extent.

66. Contusions of Intestine.—Lillienfeld has operated in 4 cases of laceration of the intestine from abdominal contusions in the last three years. One of the patients recovered after laparotomy with extensive drainage and rinsing of the intestine and suction drainage through the hole as large as a penny found in the cecum. The diffuse suppurative peritonitis rapidly subsided and convalescence was disturbed only by an infarct in the lung which caused transient trouble. The fistula into the cecum was closed in less than a month. The favorable outcome in this case was the more surprising, as thirty hours had elapsed after the injury from the sharp edge of a board, flung by some machinery, before the patient was received at the clinic. The feces that had escaped from the opening in the cecum were solid, and did not make their way into every nook and corner like the thinner contents of the jejunum when the small intestine is injured. No attempt was made to suture the perforation and it was retained for an artificial anus. This provided the best possible conditions for the paralyzed intestine and for the subsidence of the peritonitis, as has been frequently observed in diffuse suppurative peritonitis treated by making a large opening into the intestine with aspiration drainage if necessary and possibly also lavage of the stomach to relieve the alimentary canal further. In the case described no attempt was made to rinse out the abdominal cavity; it was merely sponged out with compresses wet with salt solution, the peritoneal exudate being swabbed up with dry sponges. This mechanical cleansing was done as cautiously as possible, supplemented by copious subcutaneous infusion of salt solution. In a fifth case the intestinal wall was merely crushed and no signs of perforation could be discovered, although there were evidences of diffuse suppurative peritonitis. The general condition was poor and no attempt was made to resect the crushed intestinal wall, as at first intended. The loop involved—the lower loop of the ileum—was wrapped in gauze and an opening made into the cecum to relieve the intestine. The copious peritoneal exudate was sponged away and the abdominal cavity drained with gauze, not rinsed. The injured loop apparently fully recuperated as the symptoms gradually subsided, and the patient was dismissed in good health in less than two months.

67. Experimental Research on Action of Radium.—Blauel remarks that the action of the radium rays is not felt below 1 cm. from the surface. Primary injury of the vessels was never observed in any of his numerous tests, but the radium rays have an injurious influence on all the tissues. The cells which are physiologically less resistant are the first to succumb. In normal tissues these susceptible cells are the more highly differentiated ones, especially the epithelial cells, and in tumors, the tumor cells. The epithelium of rabbits' kidneys exposed was the first to display evidences of injury, and in human carcinoma and sarcoma only the specific tumor cells. These findings corroborate Werner's suggestion that the action of radium is an intoxication with the products of the destruction of lecithin, as the epithelial and tumor cells are peculiarly rich in lecithin.

70. Symmetrical Swelling of the Lachrymal Glands in Leukemia.—The symmetrical swelling of the lachrymal and salivary glands, which Mikulicz first described in 1892, has many points in common with pseudoleukemia and leukemia. The patients presenting these symmetrical swellings have been followed and the connection with pseudoleukemia has been established by the further history of the cases. They ran into pseudoleukemia or leukemia of the severest type, and are probably only different degrees of the same affection, or at least have a common origin with pseudoleukemia. The causal agent is probably some hematogenic infection.

71. Total Loss of the Face.—A woman of 54 was standing on a ladder leaning against a lamp-post. The ladder was not on the hook placed to hold it, and it fell. As the woman fell with it, her chin caught on the hook and it tore out her entire lower jaw and all the soft parts above to just below the orbits. The face was left hanging like a mask on the hook, and was sent to the clinic the next day by mail. The case is illustrated and the successful results of the plastic operations which restored the woman's looks. She was fed at first through a stomach tube, but later learned to use a nursing bottle, and can now eat semi-solid food. Her speech at first was absolutely unintelligible, but she can now make herself understood. The surgeons restored most of the cheeks and proposed to make a new chin with an artificial lower jaw, but she refused any operation beyond what was absolutely necessary, and now wears a false face of vulcanized rubber, which is held in place by spectacles and a rubber band around the neck.

72. Pseudo-spastic Paresis.—Kaposi describes a case similar in some respects to those published under the heading "pseudo-spastic paresis with incessant tremor, subsequent to trauma." The patient, a young man, previously healthy, was hit on the head by the broken, flying head of a heavy hammer. The convulsions and tremor were noticed immediately as the patient fell after being struck. Kaposi discusses the nature and classification of the case.

74. Remote Results of Colopexy in Case of Large Rectal Prolapse.—Pachnio reports the recent examination of 11 cases of rectal prolapse treated by colopexy at Garrè's clinic. The prolapse recurred in 6 of the cases. The cases in which no relapse has occurred show the benefit of the colopexy when the patients can refrain from heavy work thereafter or do not have to pass through the stress of childbirth. Under other circumstances colopexy alone is liable not to be radical enough to insure a permanent cure. The remote results are known in only 22 out of the 58 cases in the literature, but a relapse was observed in 13 of these.

75. Trephining in Meningitis.—Hirschel states that two cases of suppurative meningitis have been treated by trephining at Czerny's clinic in the last seven years. In one case the meningitis was consecutive to empyema of the frontal sinus, in the other to a contusion over the right eye in a patient with erysipelas of the face. The assumption of a localized process justified the intervention in each case, but in both it failed to arrest the fatal course of the affection. Transient improvement was observed; in one case the hemiplegia subsided, but the thrombosis and softening persisted and entailed a fatal termination.

80. Injuries and Strictures of Urethra.—Schmidt here reviews a year's material at Mikulicz' clinic—a total of 140 cases of injury or stricture of the male urethra, with the remote results after treatment. This experience shows that an organic stricture is a very serious affection, as is evidenced by the high mortality and the recurrences. Improvement and cure are obtained only by long and tedious treatment in which the patient must co-operate with great perseverance. Measures to prevent development of a stricture are of the utmost importance on this account. Bougie treatment should be commenced at the slightest sign of stricture formation, and be kept up as long as necessary, with systematic, periodical examination afterward. Gonorrhea is the chief cause for these strictures. Injury from without frequently entails stricture formation, but such a stricture has better prospects of a cure from operative measures, especially from resection and suture of the urethra. Non-operative stretching is also liable to prove successful, but whether so permanent is still a question. Abrupt, violent bougie treatment should be avoided. If cautious use of the bougie does not answer the purpose, and if energetic measures are necessary, then the bladder should be punctured, with continuous drainage, or the perineum should be incised. The patient should then be referred to a specialist for further treatment. The desire to get along without a cutting operation should not be allowed to interfere with intervention in time, before local and general damage results.

82. Pavy's Quantitative Test for Sugar in Urine.—Sahli regards Pavy's titration with ammoniacal copper solution as a very simple, rapid and reliable method. He discusses the various points to bear in mind and its application in the clinic and for the general practitioner, proposing several modifications to simplify the technic. He also preaches the necessity for the practitioner to make his own sugar tests, not trusting them to a third party. Only the physician himself is able to appreciate the shades of difference in the reactions and to control them. Trusting to others for such an important element in the diagnosis is liable to avenge itself. He has recently known of an instance in which a physician treated a patient for months on the diagnosis of diabetes based on the finding of sugar by a third person. The diabetic diet had reduced the patient to an emaciated condition when it was finally discovered that there had been a mistake in regard to the discovery of sugar in the urine. The quantitative tests should also be made by the physician if he is to apply therapeutic measures understandingly.

83. **Primary Erysipelas of the Larynx.**—The diagnosis in the two cases described was difficult, but it was finally confirmed by the spreading of the erysipelas to the face. A subacute laryngitis, lasting for several weeks, had preceded it in one case, and in the other it followed the crisis in a croupous pneumonia. The clinical picture was the same as described in the text-books, except that in the second case there were no signs of stenosis.

84. **Determination of Tubercle Bacilli in Pleuritic Effusions.**—Jousset's "inoscopy" has been described in these columns. It is based on the fact that the solid particles in blood, etc., do not become precipitated, but remain in suspension until they are included in the coagulum. By digesting out the fibrin in the clot, the tubercle bacilli can be detected in the residue. Zebrowski has been testing this method of detecting tubercle bacilli and suggests a modification of it which he thinks is more reliable and much easier. It is just the reverse of the Jousset technic. He aims to prevent coagulation in the fluid and accomplishes this by adding a 0.5 per cent. solution of sodium fluorid to an equal amount of the aspirated effusion. The mixture is set aside in a cool room until the next day, when the sediment is centrifuged, and slides made according to Ziehl's technic. He has thus examined the effusion in 34 cases of pleuritis and in 2 of peritonitis. In 83 per cent. of the cases of secondary pleurisy he found tubercle bacilli and in 55 per cent. of the primary cases.

85. **Chemistry of Cancer.**—Bergell has been investigating the aminoacids in cancer tissues by Fischer's ester method as a means of determining the character of their albuminous content. He found that the albumin in the cancers examined contained an unusually large proportion of the four amino acids, and also of diamino acid, with a remarkably small proportion of leucin in comparison to other animal tissues.

101 "Mongolian Birth Marks" in European Children.—Sogen. Mongolen-Geburtsflecken der Kreuzhaut bei europ. Kindern. K. Fusljawa.
102 2 Fälle von Pachymeningitis hemorrhagica interna. P. Misch.

88. **Tuberculin Test in Children.**—Schick writes from Escherich's clinic at Vienna to urge the more general adoption of the tuberculin test in dubious cases of tuberculosis in children. It was applied in 120 cases in the clinic, the age of the children ranging from three months to 14 years. The special features of the response to the test in children are the frequency of an intense reaction at the point of injection and the length of the general reaction. This sensitiveness to small doses is the more pronounced the shorter the interval since infection.

97. **Rhythmic Jerking of the Head in Sleep.**—This habit was observed for several years in the seven children whose cases are described. When the child lay on its back the head was moved to and fro, but when it lay on its side the head was lifted from the pillow each time. The sleep was tranquil, and other signs of a nervous affection or hysteria could not be found in some of the children. The habit continued from the third year into late childhood. In one instance three of the children in a single family had this habit. One child exhibited it also during its waking hours. It seemed to be pleasurable rather than otherwise to the children affected.

105 *Tidlig bakterioskopisk Diagnose af Lunge-Tuberkulose (early diagnosis). C. A. Blume.
106 *Om Fund af Spirochæte pallida (Schaudinn). V. Jensen.

103. **Appendicitis.**—Tage-Hansen believes in early operation in appendicitis. He found pus in 23 out of 25 patients operated on last year, and the pus was putrid in all but 2 cases. Fecal concretions were found in the appendix in 10 instances. The operation was undertaken in 3 cases after one day, in 7 after two days, in 5 after four days, and in others from the fifth to the fourteenth day after the onset of symptoms. Since he has made it a rule to operate at once, except in the mildest cases, he has not lost a patient in his last series of 30 cases.

104. **Volunteer Service in the Havana Mosquito Brigade.**—Pontoppidan pays a high tribute to the work of the Americans in demonstrating the rôle of the mosquito in tropical pathology, and describes the details of his volunteer service in the mosquito brigade at Havana during the American occupation.

105. **Early Diagnosis of Pulmonary Tuberculosis.**—Blume was unable to obtain sputa for examination in several cases in which tuberculosis was suspected. He finally succeeded in obtaining material by scraping the larynx with a cotton wound probe, and was able to detect tubercle bacilli in the mucus thus obtained from the throat.

106. **Spirochetes in Syphilis.**—Jansen reports confirmatory findings of spirochetes in syphilis and their absence in control cases.

Original Articles

THE PATHOLOGY OF INTESTINAL AMEBIASIS.*

PAUL G. WOOLLEY, M.D.
Director, Serum Laboratory; Pathologist, St. Paul's Hospital.
AND
W. E. MUSGRAVE, M.D.
Pathologist, Biological Laboratory; Physician-in-Chief, St. Paul's Hospital.
MANILA, P. I.

In former papers, one of us (Musgrave) has dealt with the subjects of the cultivation of amebas, and the etiology, diagnosis, prognosis and treatment of intestinal amebiasis. To complete the series, there remained, then, the pathology, complications and sequelæ, and to the pathology of the intestinal amebic disease the following remarks will be limited.

It may be well to state at the outset that we can see no valid reason for departing from the nomenclature of Lösch. He described a *pathogenic* ameba from a diseased intestine and called it *Amœba coli.* Why this term should be applied to a supposititious non-pathogenic organism is difficult to say. We shall, in referring to the cause of intestinal amebiasis, use the name introduced by Lösch.

Among the many articles in the literature of amebiasis, there are but few which are of special value from the pathologic side. Chief among these are those of Councilman and Lafleur,[1] Harris,[2] Howard,[3] and Rogers.[4] Taken together, these works give a very complete picture of the disease as we have seen it.

The material has been obtained from various sources, among which have been the First Reserve Hospital (the records of Strong and Musgrave), Bilibid Prison and the Civil Hospital, all in Manila. Other material has been obtained from the private practices of Drs. McDill and Musgrave, also in Manila.

METHODS.

Bits of tissue from autopsies were fixed in Zenker's solution, in absolute alcohol, Flemming's solution, and Kaiserling, and ultimately imbedded in paraffin.

Sections from alcohol tissues were stained by Mallory's thionin and oxalic method, those from Flemming's solution in safranin and safranin-picro-indigo-carmin, those from Zenker's in Magenta-picro-indigo-carmin (Borrel), Gentian-violet-picro-indigo-carmin, eosin-methylene-blue, eosin and toluidin blue, hematoxylin and eosin, hematoxylin and picro-fuchsin (Van Gieson), chlorid of iron hematoxylin (Mallory), and Heidenhain's iron hematoxylin.

After some preliminary staining it was evident that for simple diagnosis of amebas from alcohol tissues, the eosin-toluidin-blue and thionin-oxalic-acid methods were satisfactory in the order given; for others, sublimate or chrome tissues, hematoxylin and eosin were most useful. It was evident, however, that for careful examination and cytologic study the best results could be obtained with Heidenhain's iron hematoxylin and Borrel's stain, or in the case of Flemming's solution sections with safranin-picro-indigo-carmin. Borrel's method may be modified by using gentian violet in the place of magenta with excellent results.

Borrel's staining gives most brilliant results in sublimate tissues producing very clear distinct pictures and only surpassed in clearness and delicacy by Heidenhain's iron hematoxylin. Both of these stains have the additional advantage of showing the bacteria when differentiation is properly carried out.

Hematoxylin and eosin is a very satisfactory routine method for demonstrating the amebas although the contrasts are not so distinct and the finer elements can not be so well demonstrated.

Harris' method, when applied to sections of the intestine, gives a considerable contrast between the amebas and other cells. By its use the organisms are easily found with the lower powers of the microscope.

Kaiserling tissues respond best to hematoxylin and eosin, but are of little comparative value for detail, and have been used almost exclusively to demonstrate the lesions in a gross microscopic way. From such tissues, serial sections have been made of various types of lesions and their form and extent studied in that way.

GROSS LESIONS.

Many writers say that the macroscopic lesions of intestinal amebiasis are pathognomonic. While in certain cases—perhaps in the majority—this is true, there are others in which the picture may be very deceptive. We have seen cases from the appearance of which at autopsy we could not say definitely whether or not we were dealing with amebiasis, tuberculosis or some other ulcerative condition. We have seen some cases, few to be sure, in which the majority of the ulcers were not of the classical undermined type, in which the undermining was either incipient or healing was in progress. A truly pathognomonic picture, however, is presented when the mucous membrane shows all the types of lesions, and this is not uncommon, and in which the walls of the gut are thickened and edematous.

The various lesions may not be sharply distinguished, for the process is a progressive one, and one type shades into another very gradually, so that it is for purposes of convenience in description that we shall apply epithets to arbitrary stages of the gross process.

---

* At the joint meeting of the Section on Pathology and Physiology and the Section on Practice of Medicine at the Fifty-sixth Annual Session, July, 1905, this paper was read in abbreviated form by Dr. Musgrave in connection with the article on Amebiasis which was published in THE JOURNAL Sept. 16, 1905.

1. *Preulcerative Lesions.*—These are the "small raised dots" of Rogers. They vary in size from 0.5 to 2.0 mm. in diameter and are intensely congested. As a matter of fact, when studied macroscopically, they are seen to be composed of one or more capillary hemorrhages into the intraglandular tissue. Usually associated with this condition is one of erosion of the superficial layers of the mucous membrane. These erosions, however, may be encountered in the absence of any marked congestion, although a moderate injection, at least, is the rule. With both of these processes there is little of the marked thickening of the submucosa that is so constantly seen in the more active ulcerative stages of the disease. These early lesions may be seen in any portion of the affected gut. By using the sigmoidoscope we have demonstrated them low down in the rectum within a couple of inches of the anus. They are most frequently encountered and are most numerous in the more acute cases, but may be seen also in quite chronic ones.

2. *Ulceration.*—A.—Type of Harris: These lesions, though rarer than the classic type, are nevertheless not uncommon. They are possibly the result of the process of erosion mentioned above and are primarily confined entirely to the mucous membrane. As Harris says, they "generally reach into the submucosa and rarely to the circular muscle, but never deeper." They probably commence as a very circumscribed erosion and spread laterally as rapidly as they do downward. Macroscopically, the edges are abrupt, sometimes giving the ulcer a "punched-out" appearance. They are round or oval in form and their edges are usually thickened and marked by intense congestion. Their bases are comparatively clean, grayish and edematous. They are often situated on the apices of intestinal folds and have a tendency to increase in the direction of the short axis of the bowel. This type of ulcer has a general distribution and may be encountered in any part of the bowel. It is less frequently seen in the more advanced and very chronic stages. The fact that it is most common in those bowels that show the preulceration lesion speaks for its being intermediate between the very early petechial lesions and the undermined ulcer. This is the type most common in the ileum.

B.—Classic or Undermined Ulcers: These are seen in an early stage as minute yellowish or grayish spots in the mucosa of the bowel, frequently at the centers of the petechiæ spoken of as the preulcerative stage of the disease, and are usually surrounded by a zone of congestion more or less well marked as the case may be. These spots represent the mouths, filled with necrotic material, of passages leading to larger or smaller cavities in the submucosa, which are also filled with the same material. As the process extends, the pocket in the submucosa is enlarged parallel with the surface in all directions, and, although the necrobiosis eventually involves all the coats of the bowel, the muscular layers and the mucous membranes suffer less rapidly, so that there results an ulcer with its base on the circular muscle and with overhanging edges of mucous membrane. Such ulcers may be of sizes varying from that of a pinhead up to that of the palm of the hand, and may occur in any part of the large intestine and even in the lower part of the ileum, though in the latter they are smaller.

During the process of ulceration, the submucosa becomes generally thickened and edematous, as may also the muscular layers and the peritoneal coats.

During extension, such ulcers may coalesce beneath or on the surface, and it is no rare thing to find even small submucous pouches communicating with each other by small tunnels, while the mucous membrane may show no more than a catarrhal condition.

In many of the larger lesions, the circular muscle fibers are exposed, forming the base of an ulcer, and shreds of this may be seen nearly separated from the rest, and these shreds may be removed by gentle scraping. In still more extensive cases the muscular layer may become necrosed or even perforated, and the ulcer may then be bounded externally by the peritoneum or omentum.

There are, perhaps, few diseases in which the omentum plays so important a protective part as in the one under discussion. Very early in the ulcerative stages this membrane may be found plastered on the peritoneal surface of the gut in preparation for the accidents that may follow.

Because of this function of the omentum, localized suppurations are common. Ulcers may also perforate into the subperitoneum at almost any point, and the abscess usually remains circumscribed or may furrow widely. In one case of this class, a furrowing abscess had perforated into the retroperitoneum in the cecal region and had extended upward and perforated into the right pleural cavity.

3. *Healing.*—As healing takes place, the mucous membrane gradually extends from the margins, so that in the early stages the ulcer seems to be lined with epithelium, except on its base. In the case of very small ulcers there may be complete repair, in other more advanced cases there is considerable formation of scar tissue which may lead to contractions. This we have not seen. The commonest outcome in cases of long duration, especially in those not treated systematically and continuously, is the establishment of a chronic catarrhal condition, with subsequent atrophy—a condition of chronic atrophic enteritis. This is recognized in various parts of the world as sprue or psilosis. It is not a result of amebiasis only, although it may be so in imperfectly treated cases. The gross features of the bowel in such a condition are thinness, absence of normal folds, atrophy of the mucous membrane and increased length. Combined with this atrophic condition may be one of localized hypertrophy, resulting in the formation of more or less well developed polypi.

EPITOME OF THE GROSS APPEARANCES.

In a general way, the process studied is as follows: In the early stages of the disease there occurs a catarrhal condition of the mucous membrane, with hypertrophy and cystic and mucoid degeneration. At various points, from the lower part of the ileum to the lower part of the rectum, small raised hemorrhagic spots occur, which later lose their mucous coverings and resemble erosions, and later still ulcerate. If abscesses have formed in the submucosa, they rupture into the bowel and form the early stage of undermined ulcers. The ulcers resulting from simple erosions are not, as a rule at least, of the undermined type, but they may become so. Undermined ulcers are usually, while the cause persists, progressive.

When secondary infections occur, the processes of the disease may be modified by diffuse congestion, hemorrhage, diphtheritis or gangrene. Perforations may occur in the course of the ulcerative stages of the disease, with resulting localized or general peritonitis, retroperitoneal abscess, etc.

The healing of small lesions may occur with complete repair, or of large lesions with the formation of scar tissue and with subsequent contractions. Peritonitis may result in the formation of adhesions. Complete cure may be the eventual outcome, or a condition of chronic atrophic enteritis or chronic catarrhal enteritis may result.

Generally, and probably always in active cases, the intestine is thickened. This increase may be due to edema of all the layers, but chiefly of the submucosa. It may also be due to the presence of the abscesses and sinuses which are so common in that layer. In very severe cases the subperitoneal coat may be very much thickened, mostly from edema. The mucous membrane between the ulcers in uncomplicated cases usually appears normal.

DISTRIBUTION OF THE LESIONS.

There seems to be only a partial unanimity regarding the extent and localization of the lesions in the disease. To take recent remarks on the subject, Futcher[5] says that the rectum in a majority of cases is uninvolved or is so only to a slight extent. Harris[2] remarks that in fully half the cases the lesions do not extend above the beginning of the transverse colon, and Rogers[4] writes that almost invariably the lesions are more marked in the cecum and ascending colon and frequently are limited to these areas.

In considering the presence of lesions above the ileocecal valve, Futcher says that in two of 119 cases slight superficial ulceration was present in the last few centimeters of the small intestine. Rogers concludes that "the process never invades the ileum, which is contrary to frequent results in other forms of dysentery." Many writers speak of the more or less frequent involvement of the appendix. Such observations taken from literature might be multiplied many times, but these serve to show how different are the results of careful and accurate observations based on studies carried out in different countries and even in different parts of the same country.

STATISTICS.

Our statistics are based on two series of cases, each of which comprises one hundred cases.

Series A is composed of cases in which the treatment was either unsystematic by enemas or none at all.

Series B is composed of cases treated by rectal injections.

SERIES A.

Entire large bowel involved (except extreme lower part of rectum)	87
Lesions confined to cecum and ascending colon	5
Lesions confined to transverse colon	1
Lesions confined to descending colon, sigmoid and rectum	0
Not recorded	7
	100
Appendix ulcerated (with large intestine)	6
Ileum ulcerated (with large intestine)	2

SERIES B.

Entire large bowel involved	72
Cecum and ascending colon	18
Descending colon, sigmoid and rectum	9
Transverse colon	1
	100
Appendix involved (with large intestine)	8
Ileum involved (with large intestine)	5

The variations shown in the two series, and those in literature as well perhaps, may be at least partly explained. The factors to be considered are the duration of the disease at the time of death, the kind of treatment, its duration and the stage of the disease in which the patient was when treatment was commenced.

If we take the Johns Hopkins Hospital series as an example, we may be reasonably sure that the majority, if not all, of these patients were treated by irrigations by rectum, as in our cases of Series B. A rational consequence of this might be that in many cases the lower lesions in the bowel had healed, and at autopsy only those that were inaccessible to treatment or which irrigations had not reached would be seen. This undoubtedly accounts, in part, for the variations manifested in our series, and this dissimilarity would undoubtedly be more prominent had a larger number been properly, consistently and persistently treated.

The duration of the disease at the time of death is unquestionably an exceedingly important factor in untreated cases and in those in which irrigation has been neglected. It may be said that without treatment the greater the duration of the disease the more extensive is the distribution of the lesions.

For the reasons indicated and for other obvious ones, it may be said that the findings at necropsy can not be taken as a guide to the distribution of the lesions at any period save that immediately preceding death.

We have selected from our series twenty-five cases in which death occurred from intercurrent disease early in the amebic process, and find that among these there is an increased proportion of cases showing ulceration confined to a portion of the intestine and a coincident decrease in the number showing ulceration throughout the large gut.

Ulceration confined to the cecum and ascending colon	11
Ulceration confined to the descending colon, sigmoid and rectum	8
Ulceration throughout the bowel	6
	25

Lesions of the small intestine, in our experience, have always been confined to the lower ileum and have been the apparent result of direct extension from the cecum, which is usually severely ulcerated in these cases. We have had one case in which ulceration extended 32 cm. above the ileocecal valve, but ordinarily the lesions consist of one or a few ulcers immediately above, or within 5 c.c. of, Bauhin's valve. When, however, there is a diphtheritis of the cecum, the membranous exudate more often extends above the valve for a longer or shorter distance, but without ulceration. In such cases amebas have not been demonstrated, and consequently the cases have not been included in our statistics.

As in the small intestine, so in the appendix, only cases with distinct ulcerative processes, in which amebas were demonstrated, have been included in our statistics. In many necropsies, this organ was found clinically diseased from causes other than amebiasis and occasionally showed an acute process which could not be proved to be due to amebas. All such cases have been excluded from the tables.

HISTOLOGY.

In general it may be said that the mucous membrane between the ulcers is but little changed. In many places no changes from normal can be noted. In the immediate neighborhood of the lesions, however, there is a tendency to hypertrophy, with mucoid degeneration and even cyst formation. The latter is less common in the cases we have studied than in those reported by Councilman and Lafleur. The most common change in the mucosa is in the immediate vicinity of the lesions and is shown by a tendency to more diffuse staining than is seen in normal epithelial cells; and whenever this, perhaps a sign of incipient coagulative necrosis, is seen, there is usually some distortion of the glands beneath the surface. Such changes are most frequently seen in the very early stages. In many cases, the cells lining the glands are separated from the basement membrane and lie singly or in clumps in the lumen. Under such circumstances it is not uncommon to see amebas lying among the desquamated epithelial cells or forcing their way between such cells and the basement membrane.

---

[5] The Journal A. M. A., Aug. 22, 1903, p. 480.

The most marked feature of the early lesions is congestion, often combined with capillary hemorrhages which are most noticeable immediately beneath the mucosa. This congestion may extend even to the submucosa, in which layer there is also a certain degree of thickening due chiefly to edema. Together with congestion, there is an increase of cellular elements of the lymphoid type in the interglandular tissue. The muscularis mucosa at this stage of the disease may show no changes or only a slight edema.

The most interesting feature of this early process lies in the distribution of the amebas. Not only may they be seen in the glands as described above, but they may also be present, sometimes in large numbers, in the interglandular tissues and blood vessels, in the muscularis mucosa and in the dilated veins of the submucosa, and this with changes scarcely perceptible to the naked eye or if only the low powers of the microscope are used. *In such lesions, bacteria are very few in number and often can not be found even after prolonged search, and none can be demonstrated in the amebas.* These show even in the blood vessels the peculiar rod-shaped or crystalline bodies that stain intensely with magenta and hematoxylin, the radiate structure of the ecto-plasm and ingested cells.

In sections from lesions slightly more advanced and showing a more extensive, though still superficial, necrosis, the glands immediately surrounding the lesions are hypertrophied and the cells show mucoid degeneration. There is the same lymphoid infiltration, with, if anything, a greater congestion. In the congested area each gland mouth seems to be surrounded by a zone of hemorrhages. The cells of the necrotic mucous membrane are incorporated, with occasional leucocytes, granular detritus, amebas and bacteria, into a more or less well-formed membrane. There is a more extensive separation of the glandular cells, and in such glands amebas usually can be seen either in the lumina or between the cells and the basement membrane. Within the interglandular connective tissue amebas may also be seen in the blood vessels and lymph spaces. As the process progresses and as the lesions become more advanced, the effect on the submucosa is more marked. The congestion is augmented, the edema is increased and the number of amebas is greater. There is usually also an increase in the mucoid changes of the epithelium surrounding the lesion. On the contrary, in a few cases we have seen a very low, atrophic mucous membrane and a comparatively thin-walled gut, although there were extensive ulcerations. It is reasonable to suppose that we were dealing in such cases with an infection of a bowel previously the seat of a chronic enteritis. In all the cases that we have studied, regardless of the state of the mucous membrane or submucosa, we have seen an extensive lymphoid cell infiltration and at least a moderate hypertrophy of the lymphoid apparatus.

In all lesions, whether early or late, the character of the cellular infiltration is the same in uncomplicated cases. It seems, if amebas can be demonstrated in the tissues and if at the same time there is a polymorphonuclear infiltration, that bacteria are playing an active part in the process, especially if with the infiltration there is any degree of nuclear fragmentation. In certain cases, infiltration with polymorphous leucocytes may be seen about the margins of the ulcers, although at the base of the lesions and in the submucosa they were present in but inconsiderable numbers. In some cases, although there were some, or even many, bacteria present, there was no process that seemed to be directly attributable to these. It is possible that in such cases these were simply the non-pathogenic, harmless commensals of the amebas. In others, bacteria seemed to play at least as important a rôle as the amebas, noticeably in those cases in which there was diphtheritis and gangrene. It may be that the bacteria play an important part in determining whether or not hemorrhages shall occur, for it is certain that in uncomplicated cases thrombosis is a common and early occurrence. In many very early cases the interglandular vessels of the submucosa may be seen generally thrombosed. If an ulcer is filled with a diphtheritic slough which is carried away suddenly, the chances of the hemorrhages are much increased, as is the case in typhoid.

Usually the necrotic process extends for some distance beyond the ulceration and often beyond the amebas, but in many instances amebas seem to be present in healthy tissue, notably in the early lesions. It is a question whether this necrobiosis is the result of some secretion of amebas or whether it depends more on thrombosis. In some places one seems to be the predominating factor, in others the other, while in still others neither appears to be such. It is certain, however, that the thrombosis assists the amebas in extending their zone of action, as it may likewise assist the bacteria.

Necessarily the contents of the ulcers vary according to the degree of ulceration and to the character of the bacteria present. In uncomplicated cases, which microscopically show a rather clear, yellowish, gelatinous material in the opening, the ulcer contents are composed of a granular base of albuminous character, in which cells in various stages of degeneration are imbedded, together with amebas, bacteria and usually a few red blood corpuscles.

In all the lesions the amebas vary widely in size. Measured with a Zeiss-Scheiben micrometer, they range between 4 and 35 microns.

In the earlier stages of the amebic invasion, the edema affects the submucosa. In the later ones, the subperitoneal coat is also involved and adds considerably to the thickness of the gut. Eosinophiles are not uncommon in either the modified or unmodified amebic process. They occur, for the most part, in tissues at some distance from the lesions, usually in the neighborhood of blood vessels, and are not uncommonly encountered in the subperitoneal connective tissue when that layer has become edematous. These are, perhaps, more numerous in the secondary infections, as are also mast cells. Plasma cells are frequently seen in the submucosa. In the most extensive ulcerations the picture is modified only by the extent of the process. Whether the ulcers are undermined or not, there is always the same appearance of coagulative necrosis, with lymphoid infiltration, congestion and thrombosis, and comparatively little leucocytic invasion.

The two most evident features of the intestinal lesions, when viewed with a comparatively low power of the microscope, are the necrobiosis and the relative infrequence of leucocytes, features which suggest the important rôle of the amebas, for ordinarily in bacterial infection there is an associated local leucocytosis of varying intensity. A point of some importance is brought out by the fact that in the very early lesions—

the preulcerative stage—the amebas may be encountered not merely in the glands, but beneath the epithelium and within the lymph spaces and blood vessels of the interglandular tissue and the submucosa.

THE CHARACTER OF AMEBAS IN SECTIONS.

In toluidin blue and eosin the ectosarc stains fairly definitely and the vacuoles of the protoplasm show well. The bacteria also stain, as do the encysted bodies and fragments. The nucleus is very definitely stained and surrounded by a more or less distinct perinuclear space. The nuclear membrane is a clear deep blue. The nuclear protoplasm is pink and contains one or several deep blue-black bodies, or perhaps none. There may be several dark-stained thickenings in the nuclear membrane. As a rule, in well-stained sections the amebas, where they do not contain much extraneous material, such as bacteria and nuclear detritus, are less deeply stained than the cells of the intestinal mucous membrane. The protoplasm of those deep in the tissues is less intensely stained than that of those in the mucous membrane, and it may be that this phenomenon is due to the fact that in the more superficial layers the organisms have taken up more mucous material. That there is some reason for this supposition is shown by the fact that this stain is much less useful in studying the organisms in liver abscesses, where, of course, there is no mucus.

Perhaps the most brilliant stain for amebas in tissues is that of Borrel. This consists of:

1. Saturated aqueous solution of Magenta red.
2. Saturated aqueous solution of picric acid. Saturated aqueous solution of indigo carmin aa.

Stain with No. 1 for 20 minutes and wash.

Stain with No. 2 for 5 minutes, wash and differentiate with alcohol, xylol and balsam.

With this the amebas are not so readily distinguished by the low powers of the microscope as with the thionin or eosin toluidin-blue stain, but the finer organization is much more easily studied with high powers. Generally, with this stain the amebas are less deeply colored than the surrounding tissues, being a rather pale bluish or purple, or, in well decolorized specimens, of a greenish hue. The edge of the organisms shows as a fine blue line, which is more distinct about the body of the parasite and less distinct about the pseudopodia. The ectoplasm appears as a finely reticular or almost hyaline substance, the fibrillar or granular part of which is stained a very faint blue. The endosarc appears as a granular material more deeply stained than the ectosarc, and purplish, bluish or greenish, according to the degree of decolorization. Within this are spaces which remain uncolored, though in thick sections they have a bluish tint due to the underlying stained material. There may be bacteria also in the endosarc. There are also the rods of which Councilman and Lafleur speak, which are not seen in all cases, occurring in those in which there is more extensive sloughing or diphtheritis. It may be that these are crystalline, derived from the blood, or Charcot-Leyden crystals, which are occasionally found in leucocytes in certain conditions, and which Askanazy[6] says are oxyphilic.

The nucleus may be surrounded entirely or in part by a clear perinuclear space. The general color of the nucleus is violet or purplish. The outlines are sharp, and, if the section is not too decolorized, should be a clear crimson, which may be in the form of a complete ring or of an incomplete one, or may be nodulated on its inner surface, corresponding to thickenings in the chromatin. There are also occasionally crimson granules within the nucleus and occasionally one perfectly round mass corresponding to the nucleolus.

Ingested cells, such as red blood corpuscles, leucocytes, etc., may also be seen within the protoplasm in various stages of degeneration, the stain depending on the extent of the process.

In sections so decolorized that the magenta is all removed, the nucleus appears a blue color deeper than the tint of the rest of the cell and with the chromatin material still more deeply stained.

Heidenhain's iron hematoxylin is as excellent a stain for amebas as it is for other tissues, although not so brilliant as the magenta-picro-indigo carmin. In carefully manipulated sections the nucleus of the amebas is somewhat more deeply stained than the cystoplasm and ordinarily appears as a dense blue-black ring, in the center of which is the round black nucleolus. The nuclear plasma is usually just of a blue tint and is divided by a mesh of delicate dark reticulum. There may be other deeply stained chromatic elements or granules within this. The radial striæ of the cytoplasm is well shown and the crystalline bodies are, when present, an intense black. The spongioplasm appears as a network of dark lines and the cell boundary is sharply differentiated. Red cells, when present, stain according to the state of degeneration, those most recently ingested being black, those least recently yellowish. Bacteria. when present, stain sharply and distinctly, when not too far degenerated or digested.

Amebas grown in cultures from amebic ulcers, when stained by Borrel's method, show somewhat different staining reactions.

Cover-glass impressions may be made in the following way:

A cover-glass is placed on the growths on agar plates, removed quickly and instantly plunged into a very hot saturated solution of mercuric bichlorid. They are then washed in Gram's solution or a weak tincture of iodin, and rinsed in 80 per cent. alcohol, after which they are washed in water. The stain is then applied in the usual way. After this process the preparations are differentiated in alcohol, cleared in xylol and mounted in xylol-damar. The amebas are seen in various conditions, as they were in the culture, and of various shapes and sizes. In many the pseudopodia have not been withdrawn and can be well seen. Under these circumstances the ectosarc has a pale, diffuse, blue color, or is perhaps very finely granular and has a very sharply differentiated limiting line. Usually, however, this is not well seen and the whole organism has a sharply circumscribed, blue, granular appearance. The contractile vacuole shows clearly as an unstained, ovoid or oval space, usually near the surface of the organism, but occasionally near the nucleus.

The nucleus is composed of a round, central, deep purple body, surrounded by a narrow, pale bluish, homogeneous zone, and this, in turn, is surrounded by a denser, blue, granular zone. About this, in turn, is ordinarily a second more or less faintly stained zone. The whole nuclear body is round or slightly oval. The nucleolus is always round.

Comparing the amebas in such preparations with those in sections, we can readily see that the relative size of the nucleus is the same, as is also the relation between the protoplasm and nucleus; but in the tissues the contractile vacuole is usually not so distinct and the nucleus does not present the same appearance. This may be due to the fixation or it may be due to the different degree of decolorization. The dissimilar nutritive conditions may also affect the microchemical staining reactions.

---

[6] Munch. med. Wochft., 1904, vol. li, 1945.

The small amebas, those the size of an erythrocyte or smaller, should show the same relation in the size of nucleus and cell body.

The distinguishing feature of the amebas is their generally irregular or oval shape, though they are often round, their relatively small, round nucleus, and the larger amount of granular or vacuolated protoplasm, which often contains foreign bodies.

RELATION OF THE AMEBAS TO THE TISSUES.

The Mucous Membrane.—It is not known whether the amebas are able to attack or to pass through an intact mucous membrane; in fact, it seems probable that in order for them to enter the deeper layers of the intestine there is some change from the normal (Schaudin). It is possible that catarrhal conditions, however slight, are accompanied by erosion, or necrosis of even a few, of the superficial cells, and would offer the necessary conditions for invasion. It is, at any rate, certain that the amebas have less influence on the epithelial cells than on the supporting tissue. That this is true may be demonstrated repeatedly. In many glands the amebas may be seen either in the lumen or between the lining cells and the basement membrane. As a rule in these cases the epithelium detached has lost no more of its normal character than might be expected, and if adherent it seems more healthy than would be imagined in the presence of an organism whose power of causing cellular destruction is as great as it is in the case of the ameba. Generally speaking, epithelium seems to have as great resistance to the ameba as has muscular tissue.

Muscle.—In all works on amebiasis attention has been called to the lack of resistance the connective tissue offers to the progress of the organisms. Attention has been repeatedly called to the fact that the extensive ulcerations are in form and situation dependent on this quality in the submucous layer of the intestinal wall. The preliminary feature of the changes in this position is edema, which, after invasion by the amebas, is followed by swelling of the fibers and cells, infiltration with round cells and lymphocytes, sometimes accompanied by fibrin formation. The nuclei of the swollen cells become paler, the appearance of fibrillation is lost and the tissue becomes hyaline or necrobiotic. A further feature of the process is that new tissue is found early and this has the appearance of granulation tissue. Suppuration, as previously indicated, probably does not occur in the uncomplicated disease.

Blood Vessels.—Just how the organisms enter the blood vessels can not be satisfactorily stated. In some sections they are seen in these vessels in large numbers, in the same or others they may be seen in the perivascular lymph spaces or they may appear immediately beside the endothelium of the capillaries. It is possible that they enter directly through the capillary walls by virtue of their inherent power of progression, in much the same way as the leucocytes wander in and out. There is the possibility that in the process of tissue destruction the vessel walls are so changed as to make this process more practicable, or that following capillary hemorrhages and before coagulation had occurred the organisms may enter the vessels and make their way along. Certain it is that they do not necessarily cause thrombosis by their presence, although this appearance is by no means uncommon in tissues, and especially in the vessels of the interglandular tissues. So far as the blood cells are concerned, the amebas are able to ingest and to destroy apparently healthy erythrocytes and leucocytes.

Cells.—It was shown by Councilman and Lafleur, and forcibly insisted on by Howard, that leucocytic infiltration is not a feature of amebiasis. On the contrary, it is stated that the process is more in the nature of a subacute or chronic inflammation, in that the cells predominating in the infiltration are formative ones and lymphocytes. In addition to these last mentioned cells there is often a considerable number of eosinophiles, though this is not the rule. If the condition is a chronic inflammatory one, however, then this is the type of infiltration we should expect, for lymphocytes and eosinophiles are the cells which, par excellence, occur in such pathologic states.[7]

In one series of sections we saw considerable numbers of mast cells, which occurred chiefly in the glandular layer of the bowel. On what conditions the presence of these depends we can not say, except to note that in the bowel from which the sections were made there was considerable diphtheritis.

Plasma cells are not uncommonly seen in the submucosa, as Councilman and Lafleur state. If these cells are of lymphoid origin, we should expect them to be frequently met in subacute or chronic inflammation in which there is a proliferation of, and invasion with, lymphoid cells.

RELATION OF AMEBIAS TO BACTERIA.

From our experience it can not be said that the presence of bacteria limit the field of activity of the amebas. As a matter of fact the organisms seem to be about as numerous in cases complicated by bacterial superinfections as in uncomplicated ones, unless it be in those in which pyogenic cocci are present. In one case so complicated there were certainly fewer amebas in the lesions and there was very active leucocytic infiltration with marked coincident karyorhexis, a very uncommon picture for amebiasis.

When amebas are found in exudates rich in bacteria they show evidence within their bodies of a very active phagocytosis.

CONCLUSIONS.

1. Intestinal amebiasis is a peculiar ulcerative condition of the intestine caused by Amœba coli (Lösch) usually confined to the large intestine, though occasionally (7 in 200 cases) the ileum is affected and more often (14 in 200 cases) the appendix is involved.
2. In the majority of cases the condition affects the entire bowel (159 in 200 cases), though it may be limited to one or more portions, most commonly the cecum and ascending colon (23 in 200 cases).
3. The ulcers show a tendency to be undermined, due to the lack of resistance on the part of the submucous layer of the bowel.
4. The organisms may enter the blood vessels very early in the disease and may be transported to the submucosa without lesions of the muscularis mucosa.
5. The disease is a subacute chronic inflammatory process, as shown by the character of the exudate and infiltration, by the early formation of granulation tissue and by the absence of leucocytic infiltration.

6. Complete healing may be accomplished, or a condition of chronic atrophic enteritis or chronic catarrh may persist, which is known as sprue or psilosis.

The photographs and photomicrographs were made by the Government Photographer, Mr. Martin. The colored drawing (27) was done by Dr. W. B. Wherry. The other colored drawings were made by Mr. Espinosa, the artist of the Bureau of Government Laboratories. To these gentlemen we take occasion to express our thanks.

THE CORRODING PROCESS OF THE OVUM IN ITS IMPLANTATION IN THE FALLOPIAN TUBE, A SOURCE OF HEMORRHAGE IN TUBAL PREGNANCY.*

J. RIDDLE GOFFE, M.D.
Professor of Gynecology, New York Polyclinic.
NEW YORK.

The surgical history of ectopic pregnancy is dotted with puzzling cases in which undoubted symptoms of the condition were present, and in which on operation a greater or less quantity of blood was discovered in the pelvis, and yet careful microscopic examination of the tissues removed failed to show any trace of the products of conception. In many of these cases careful examination has failed to disclose the source of hemorrhage.

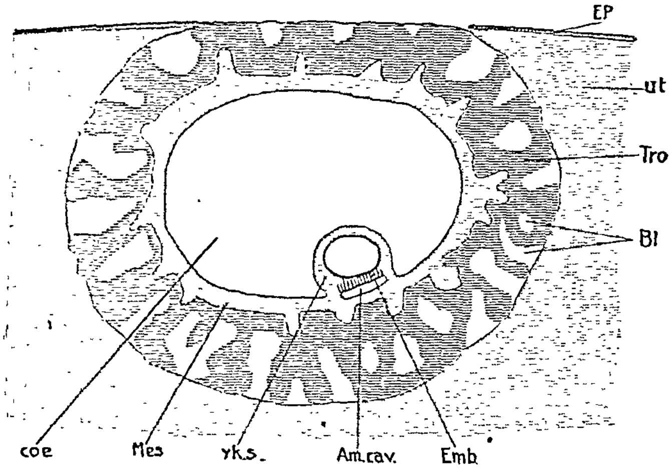
Some recent studies in biology bearing on the implantation of the ovum in the uterine mucosa have revealed a process which when transplanted, as in tubal pregnancy, sheds a flood of light on many of these obscure cases. The established teaching has been that the impregnated ovum when it reaches the uterine mucosa nestles among its follicles, which at once take on a hypertrophic development, reach out on all sides and envelop it in their arms. Later developments bring into existence the chorionic villi, the intervillous spaces and the entire mechanism of nutrition. The process of attachment of the ovum to the uterus is known now to be the work of the ovum itself. The ovum is the active agent, and embryologists designate this early attachment by the term implantation.

It may be of interest and perhaps instruction at this point to go quite fully into the details of this process. What I shall say has been gathered almost entirely from an address on the subject by Professor Minot[1] of Harvard Medical School, at the meeting last year of the American Gynecological Society. It has been discovered that certain tissues possess the property of attacking and destroying other tissues. This faculty consists in a process of digestion and is supposed to be chemical in character, from which the tissue itself does not suffer, but which will destroy other tissues with which it comes in contact. The destructive process of the phagocytes is doubtless analogous. It is known that certain young tissues of the embryo are endowed with this capacity, and, while it has not been absolutely demonstrated that the human embryo possesses it, the observations on the embryos of lower animals confirmed by less complete studies of the embryo of man lead to the belief that such a phenomenon attends the implantation of the human ovum.

The process of implantation as observed by Minot and others in various animals is as follows: The ectoderm of the chorion undergoes a peculiar proliferation by which its cells become very much more numerous. Some of the cells rapidly assume a distinctive character and are easily recognized by their large size. This layer of ectodermic cells is called by Minot the trophoderm. Wherever these modified ectodermic cells come in contact with the walls of the uterus, destructive changes go on in the uterine tissue, producing a cavity in which the ovum lodges itself. The trophoderm then undergoes a hypertrophic degeneration, producing a series of irregular spaces which persist and become the intervillous spaces of the placenta. Papillary outgrowths of the chorionic mesoderm meanwhile penetrate the trophoderm, initiating the formation of the chorionic villi.[2]

The earliest stage of the human ovum yet secured for observation and described is presented in the work of Peters, and is known as Peters' ovum. The accompanying diagram is based on its description.

The effect of this corrosive action is readily conceived in cases in which the implantation of the ovum is transferred from the uterus to the thin-walled Fallopian tube. While in most instances the implantation is successfully accomplished, there must be frequent instances in which the corroding process extends completely through the wall of the tube or may bring the intervillous spaces so near to the surface that the blood pressure bursts through the peritoneum and occasions serious hemorrhage.



Explanation of diagram: Ep. uterine epithelium; Ut, mucous membrane (decidua) of the uterus; Tro, trophoderm; Bl, spaces formed by the degeneration of the trophoderm; maternal blood enters these spaces from the decidual blood vessels; Emb., embryonic shield; Am. Cav., amniotic cavity; Yk's, yolks sac, the entodermal lining of which is indicated by a heavy black line; Mes., chorionic mesoderm; Coe, extra-embryonic celom.

Such a condition first came under my observation as recorded in the following case. The history is given quite fully to illustrate the fact that this apparently simple lesion may be attended with serious or even fatal hemorrhage:

Patient.—Mrs. R., aged 33, a former patient of mine, called at my office Sept. 20, 1903, and gave the following history:

History.—She had been married 4 years and had two children, the youngest 10 months old. She is a strong, healthy woman, and had nursed both children. While nursing the first child, monthly flow came regularly every 28 days, beginning one month after parturition. With the second child an apparently regular menstruation appeared one month after parturition. It disappeared then and did not return till two months ago, July 15, when it was normal in character. In August there was no sign of menstruation, but on September 4 (16 days previous to interview) a painless natural flow began and continued for 8 or 9 days. Following this, there was indulgence in sexual intercourse on two successive nights and an unusual exaltation of sexual desire for a week or ten days. In this connection the patient said that, while ordinarily a sufficiently passionate woman, she had experienced while carrying both her children an unusual intensity of sexual desire during the first two months of pregnancy. The recurrence of this made her suspicious, although she was still nursing her child, and she called for an opinion regarding the possibility of pregnancy. A most thorough examination failed to reveal any physical signs or suggestion of pregnancy, either normal or otherwise, although I examined for both conditions. I advised a cessation of social duties, daily hours of rest in bed and prompt notification of any unusual occurrences. Occasional stains, spotting, appeared, and six days later sharp pains in the abdomen gave the impression that the regular menstruation was about to recur. Five days later, October 1, she entertained company at dinner. At the close of the function she had a sickening pain, grew pale and nearly fainted; she went to bed. October 9, she dined with her husband down town; on going home she had a bearing down pain and found that she was flowing rather freely. She remained in bed the next day, but the following day, Sunday, she got up to dinner at 1:30 and ate a hearty meal, although she had felt weak and miserable during the morning and suffered from pain in right abdomen shooting up to the shoulder. I saw her at 3 p.m.; she was in bed and was pale and pulse was weak; she had been flowing steadily since Friday.

[1] Trans. Amer. Gyn. Soc., 1904.

[2] The Harvard Medical School is forming a collection of serial sections of human embryos which is intended always to be open to competent investigators and students. Specimens are solicited, those of first and second month being especially desired. They are best preserved by prompt insertion in a mixture of formalin, one part, to nine of water.

Examination.—These symptoms and history pointing so positively toward ectopic pregnancy led to a careful examination. I could discover no enlargement of the uterus, comparing it with my recollection of its former size, but I did discover a perceptible enlargement of the right tube, although not very marked. I diagnosed unruptured tubal pregnancy, or tubal abortion of the right side.

Operation.—Directly after examination the patient suffered a sharp attack of pain and went into collapse. As soon as she had sufficiently revived she was placed in a carriage and taken to the sanitarium. Stimulants were cautiously used and she passed a comfortable night. Operation was performed at 1:30 p. m. the following day by vaginal section. After dilatation and curettage of the uterus a laceration of the cervix was closed with three chromic sutures. The usual T incision was then made in the anterior vaginal wall; the bladder stripped off and the peritoneal cavity opened. It was noticed that both the anterior and posterior vaginal fornices bulged quite markedly, and on opening into the peritoneal cavity there came a gush of liquid blood and clots. Some of the latter were dark and firm and some soft and bright, showing old and recent hemorrhage. The uterus was promptly delivered into the vagina and the right appendages brought down. The tube seemed to be intact and the fimbriated end normal in every way. The tube was enlarged and its walls thickened; there were also marked signs of congestion. On turning the tube to get a view of its posterior aspect, a small pinhole opening, through which a minute clot protruded, came into view at its middle third. The tube was rapidly quilted off and cut away—the ovary not being interfered with. After examining the appendages of the opposite side and finding them normal, the fundus uteri was restored to the pelvis and the vaginal incision closed. An opening was then made into Douglass' pouch for drainage, through which blood and clots were removed and a light gauze drain applied. Some difficulty was experienced in getting the bowels moved on the third day, but after that convalescence was normal.

Examination of Removed Tissue.—The interior of the tube gave no indication of the development of a placenta nor chorionic villi. The ovum at a very early stage must have eroded its way quite through the tube, and hemorrhages must have been quite frequent, if not almost continuous.

I cite this case as being a most interesting example of one phase of tubal pregnancy.

Paul Zweifel[3] cites a case in which hemorrhage occurred eight days after the first omission of the menses. The ovum at that stage could not rupture the tube and examination disclosed that the ovum had eroded clear through the tube and serosa into the peritoneal cavity. Whether the hemorrhage is moderate or sufficiently extensive to endanger life is a mere chance. These slight openings may or may not be attended with temperature, depending on the promptness with which aid is sought and obtained.

It would seem to be a fair inference that when a woman has skipped one menstrual period and is attacked with sharp pain in the hypogastrium, collapse, and vomiting with markedly feeble pulse, if there be no rise of temperature, an erosion through the walls of a gravid tube should be suspected at once and the necessity of prompt operation seriously contemplated.

A secondary feature of interest in my case is the fact that in less than a year after the operation in which the right tube was removed, the patient became pregnant normally and has been successfully delivered of a fine boy.

EXTRAUTERINE PREGNANCY: CASES OF UNUSUAL TYPE.[*]

J. H. CARSTENS, M.D.
DETROIT, MICH.

Many years ago physicians recognized extrauterine pregnancy and some patients actually recovered after ordinary treatment. Sometimes even then the diagnosis was made before rupture, and physicians treated these patients by killing the fetus with electricity, or morphin was injected into the sac and thus the life of the embryo was destroyed. Physicians then found patients with vague histories in whom inflammation would take place, and in the course of time an abscess would break into the rectum, bladder, or vagina, and fetal bones would pass. The physician then knew that he had a case of extrauterine pregnancy that had become infected and produced the symptoms that he was called on to treat.

With the advancement of abdominal surgery cases of extrauterine pregnancy were found during abdominal section. With the gradual development of pelvic surgery physicians were able to diagnosticate ruptured extrauterine pregnancy and by prompt operation could save a life. In fact, the general symptoms of ruptured extrauterine pregnancy are now so well known that almost every general practitioner recognizes the trouble and sends for a surgeon. There are exceptional cases, however, in which the classic symptoms of the course of the condition are absent or different and mistakes are made by very well posted diagnosticians. Having had two cases within a few days of each other of this kind, I thought a short report of these might be interesting.

Case 1.—Mrs. O. B. R., aged 30, mother of three children, youngest 3 years of age, had menstruated regularly until Nov. 20, 1904.

History.—During Christmas week, as she explained it, she had some pain and only slight menstruation. In January, 1905, another and slight show with considerable pain kept her in bed for several days. February 14 she was taken with severe pain and inflammation. Her family physician recognized a swelling on the left side and treated it on general principles. The inflammation gradually subsided, and she was able to sit up and move around a little and then it started again. This continued for nearly ten weeks. She became very much emaciated and anemic, having temperature running up to 100 or 104.5. She was finally put on a stretcher and sent to me, a distance of 150 miles. She arrived at Harper Hospital April 26, 1905, in fairly good condition, but a typical case of long-standing sepsis. Carefully going over the history, I told my assistant it looked to me like a case of extrauterine pregnancy which had ruptured in the broad ligaments and had become septic.

---

[3] Brit. Gynec. Jour., Nov., 1903.

[*] Read in the Section on Obstetrics and Diseases of Women of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Operation.—She was prepared for operation and was operated on April 27, 1905. I found a sac extensively adherent, containing a four months' fetus, with decomposed placenta and situated in the left broad ligament. The placenta could be easily removed, the sac was stitched to the lower angle of the abdominal wound and a rubber drainage tube inserted. The abdominal wound was closed with silkgut sutures.

Result.—She made a splendid uninterrupted recovery and returned home the twenty-fifth day. The power of resistance of some individuals is beyond comprehension.

Case 2.—Mrs. C. R., aged 24, mother of two children, youngest two years, was brought to Harper Hospital April, 1905, with a temperature of 104.5, and with the statement that she had had a miscarriage and that there probably was retained membrane. I examined and found a large swelling on the left side, which I diagnosticated as an abscess in the left broad ligament, and the only thing to do was to operate and to clean it out as soon as possible. The pulse being 140 and 160, no time was to be lost and no extensive operation could be done. She was given an enema.

Operation.—With a few whiffs of chloroform, an opening was quickly made with scissors into the abscess cavity, which was then increased by tearing with the fingers. Nearly a quart of pus flowed out, and decomposed tissue, which was recognized as placenta, was removed. The cavity was cleaned with sponges, not irrigated, and a rubber drainage tube inserted. She made a quick recovery, and in two weeks returned home. After she was able to talk I got the following history:

History.—She had menstruated regularly since her last child's birth until Feb. 5, 1905. She did not flow again until March 21, when she had severe pain with the menstruation. She considered herself pregnant and thought she was having a miscarriage. The pain, however, eased up somewhat. April 1 she was taken with severe pain, and continued to feel quite poorly and passed membrane from the uterus, which was supposed to be the placenta. She did not improve, however, but daily continued to get worse, fever and chills developed, physicians were changed, but her condition became steadily worse until she was brought to the hospital as above stated.

These cases could be amplified by similar ones, but they are sufficient to teach some lessons. One of these is that extrauterine pregnancy is more often met with than ordinarily expected. Another lesson is that a careful history of the onset of the disease will throw light on the subject. The patient often unintentionally throws the physician off his guard and only by persistent questioning will he get at the real facts. I would conclude, therefore:

First, that extrauterine pregnancy must always be in the physician's mind in cases of sudden onset of pelvic trouble.

Second, that the least irregularity of menstruation is suspicious of extrauterine gestation.

Third, that inflammation and sepsis following a supposed miscarriage often are due to ruptured ectopic pregnancy.

Fourth, that prompt operation is always indicated; the choice of the vaginal or abdominal route depending on circumstances.

DISCUSSION.

ON PAPERS OF DRS. GOFFE AND CARSTENS.

Dr. R. T. Gillmore, Chicago suggested that if, after curetting the uterus, the scrapings are examined microscopically for decidual cells, an early diagnosis may be made and the case need not be allowed to become septic. Of course, decidual cells may be found in other conditions than tubal pregnancy in which the endometrium is inflamed, so that the finding of the decidual cells is merely suggestive. A careful microscopic examination of the tube should be made after the operation for chorionic villi. A blood count is of value in showing whether or not hemorrhage is due to shock or anemia, in ruptured tubal pregnancy.

Dr. L. H. Dunning, Indianapolis, declared that cases of extrauterine pregnancy at full term are very rare. Some years ago he thought he had such a case, but on careful examination he found that he was mistaken, and the final conclusions were verified afterward by microscopic examination. A full term ectopic pregnancy in a tube which has not ruptured would show no covering of peritoneum continuous above. In other words, it should be free in the abdominal cavity like an ovarian or fibroid tumor. If the sac is covered posteriorly with peritoneum, then it is not an ectopic pregnancy at full term in an unruptured tube.

Dr. C. O. Thienhaus, Milwaukee, said that the fact pointed out by Dr. Goffe of the Langerhans cells eating up and gradually destroying the walls of the tube shows that extrauterine pregnancy should be classified as a true neoplasm which demands immediate operation in every case in which the diagnosis is made, no matter whether rupture has occurred or not. The only exception would be in extrauterine pregnancy of seven or eight months. In these cases it is of great scientific importance to know whether or not the fetal sac is without or within the tube. In ruptured extrauterine pregnancy it is necessary to differentiate between cases in which Nature has formed adhesions and has encapsulated the blood and the tube; in other words, those in which a hematocele is present, and cases of free abdominal hemorrhage. In this latter class are usually cases in which the rupture of the tube takes place in the neighborhood of the uterus. These cases, though rare, are the most dangerous ones, because the hemorrhage is so profuse that Nature has no time to form adhesions; and if immediate operation be not performed the patient invariably bleeds to death. In such cases it is inadvisable to transport the patients to a hospital. They should be operated on at once wherever they happen to be at that time. The operation should be done as rapidly as possible, not in deep narcosis, but during the stage of excitement of ether anesthesia. About three years ago Dr. Thienhaus saw such a case, and had the good fortune, by prompt and quick operation, performed in a farmhouse, to save the life of the patient. Dr. Thienhaus was surprised to hear in the surgical section that so much chloroform is still used, as it is a well-established fact that ether is much less dangerous than chloroform. He has discarded chloroform entirely for the past four years and has used ether in all cases. When a tumor is found lying in the neighborhood of the uterus and it is uncertain whether it is a cyst, pus sac or a hematocele, an exploratory puncture or colectomy will often aid in diagnosis, and when blood is found one can say in 95 per cent. of the cases that it is ectopic pregnancy. In cases of infected hematocele, cleaning out and draining by the vaginal route is safer than the abdominal operation.

Dr. I. B. Perkins, Denver, said that he has noticed that several of these patients appeared to have healthy tubes, and in these instances the woman had imagined herself pregnant and took medicines intended to contract the uterus and to expel its contents. Ten days or two weeks later she would suffer from a ruptured tube. It occurred to Dr. Perkins that in all probability the pregnancy had taken place in the tube, and while the ovule was making its descent toward the uterus it was arrested at the cornu, where the tube was closed temporarily by the contractions of the uterus produced by the drugs taken, and that before relaxation occurred sufficiently to allow the impregnated ovule to pass into the uterus it had developed sufficiently and had become sufficiently adherent to the tube that it could not pass. He thinks it probable that tubal pregnancy frequently occurs in this way in a normal tube, and when the rupture occurs in these cases it is usually near the cornu, and the hemorrhage and shock are great.

Dr. D. C. Brockman, Ottumwa, Iowa, reported a case of synchronous extrauterine intrauterine pregnancy. A multiparous woman consulted him with a history of persistent vomiting and temperature. She was greatly emaciated, and on examination he detected a tumor in the central part of the abdomen. Blood count was negative. The woman knew herself to be pregnant, and the central tumor was taken to be a pregnant uterus at four and a half months. On the left side was a cystic tumor, in which he could get ballottement, but no evidence of abscess showing a pregnancy in the abdomen to the left of the uterus. Hoping that he could tie off the ovarian arteries and do a panhysterectomy without fatal hemorrhage, he opened the abdomen, but found the intestines so adherent to the sac that it was impossible to reach the ovarian arteries or to do anything with the sac without causing a fatal hemorrhage. He closed the abdomen and waited a few days before he delivered the fetus through the vagina. He did not attempt to remove the placenta, which was adherent to the right side of the sac, but packed the sac full of gauze and waited for the vessels to close. On the fourth day premature labor set in, and he removed the packing, hoping to stop the labor. Anodynes failed, hemorrhage occurred, with death six days after the operation from exhaustion due to hemorrhage. Dr. Brockman finds that there are about 133 cases of this kind on record in the majority of the patients. If another case like this one came to him, he thinks he would destroy the extrauterine fetus by electricity or morphin and allow it to remain, hoping the intrauterine pregnancy would continue to term.

Dr. William E. Ground, Superior, Wis., said that ectopic pregnancy is undoubtedly a condition that exists oftener than is usually suspected. The determination of the location of the fecundated ovum is a matter of mere incident. If the ovum is arrested in the Fallopian tube, tubal pregnancy will follow; if it locates in the body or fundus of the uterus, normal pregnancy will result, and if it forms an implantation in the lower uterine zone at or near the internal os, placenta prævia will be the consequence. Rupture in cases in which the implantation is near the uterus, always occurs early. Dr. Ground had a case in which the rupture occurred at the patient's next regular menstrual period; she had never missed a period. The symptoms of internal hemorrhage were extreme. The patient was sent to the hospital and the abdomen was opened. The tube was found torn clear across near the uterine cornua and the abdominal cavity was filled with liquid and clotted blood. As Dr. Ground understands it, the decidua is a hypertrophied endometrium, and the chorionic villi is the outer fetal membrane and purely a fetal structure; therefore, in cases of extrauterine pregnancy and in the absence of intrauterine pregnancy, one would not expect to find chorionic villi in the uterine scrapings.

Dr. W. O. Henry, Omaha, said that Dr. Goffe's case reminded him of one he had, and he thinks Dr. Goffe's explanation of the cause of the hemorrhage correct. The pregnancy occurred near the fimbriated extremity of the tube, and when the abortion occurred it was not a rupture, but simply an expulsion of the contents of the tube. When the fetus is located nearer to the uterus and rupture occurs, the fetus may be extruded entirely, but the placenta remain; when it is in the outer end of the tube, however, the entire ovum with its coverings is extruded. In other cases one will find the rupture near the cornu of the uterus, and hemorrhage ensues, the fetus being retained. If there is violent hemorrhage, it is not safe to move the patient any great distance, but ordinarily it is better to operate in a hospital. Dr. Henry considers that the point made by Dr. Gillmore with reference to making a diagnosis by examining the uterine scrapings is not correct, because in extrauterine pregnancy chorionic villi are not found in the uterus; they are only found in the tube.

Dr. C. L. Bonifield, Cincinnati, briefly reported a case which seemed to be one of unruptured tubal pregnancy. After the ovarian arteries were ligated, the whole mass was lifted up from behind the uterus, to which it was adherent. On most careful examination it appeared to be an unruptured tubal pregnancy, but he is convinced that rupture occurred, that a blood clot filled in the opening, and that after regeneration of the tissues the tube took on a normal appearance. He has seen two or three cases in consultation, in which most severe hemorrhage had occurred and the patient was practically pulseless; and had been so for eight or ten hours, but subsequently improved a little. In such cases he advises leaving the patient alone for eight or ten days until the blood clot has been absorbed and the woman is in condition to stand an operation.

Dr. J. H. Carstens said that microscopic examination, once in a while, may throw some light on the subject. He agreed with Dr. Henry about taking patients to the hospital. It is a question of the individual case. If he is 100 miles from home he will not take a patient to the hospital, but will do the best he can, and he thinks that some patients recover under the most adverse circumstances. Dr. Carstens does not think that one can tell where the rupture is located. The blood does not always come down into the cul-de-sac. Sometimes there are adhesions and the blood is up in the abdomen. One can not always feel the hematocele. If the hemorrhage continues with increase in pulse rate operation would better be done quickly. If there has been a hemorrhage, followed by shock, and the pulse remains about 120, then one can wait for an opportunity to operate; but so long as the pulse continues to increase in frequency, one must operate quickly, in two minutes, if necessary. He advises cutting and putting on forceps, allowing them to remain for hours if necessary; it will not hurt the patient. When the woman has had time to recover from the shock, a thorough operation may be done. Dr. Carstens operated through the abdomen in one case because the tumor did not extend down into the vagina. It bulged out in the side and looked like a big ovarian tumor, and that was the nearest point to get at it. When pelvic inflammation comes on suddenly without any apparent cause, and after investigating the case carefully one finds that there was some irregularity in menstruation and some pain, trouble is to be looked for.

RECENT ADVANCES IN THE PHYSIOLOGY OF HUMAN NUTRITION.*

FRANK BILLINGS, M.D.
CHICAGO.

The question of the physiology of nutrition is a most important one. It is especially important to the physician, for without a clear idea of the subject he can not prescribe a proper dietary for the well or sick nor can he clearly understand the pathologic conditions which occur as a result of an improper amount or kind of food or the morbid conditions which result from malnutrition.

It is the belief of the layman and of many physicians, too, that the chief nutrition of food consists of the proteids, and meat is especially looked on as the food which affords strength and sustained effort. Among Europeans and Americans especially meat eating is very prevalent, chiefly for the reasons given above. Besides this, the palate is pleasantly excited by rich animal foods, and in consequence a larger amount is taken. It is too common a belief that the well-nourished body is the most healthy and best able to resist disease and that a large fat deposit in the tissue is an evidence of good general nutrition.

Our food is made up of proteids, fats and carbohydrates. The proteid or albumin, both animal and vegetable, is the tissue builder. Relatively, a larger amount of proteid is required for the growing individual, pound for pound, than for the adult. The fats and carbohydrates (sugars and starches) comprise the fuel of the body and supply the necessary heat and keep the machinery going.

STANDARDS OF DIET.

As a result of the years of experiment by physiologists and of observation by many workers, certain general conclusions have been arrived at in reference to the requisite amount of food which is necessary to maintain health and strength and at the same time afford the best degree of efficiency with the least expenditure of energy on the part of the body to utilize the food. The standards of diet which have been brought forward by different workers do not differ very materially in the amount of the different elements advised for a twenty-four-hour dietary. The standard of Carl Voit of Munich is the one best known and has been recognized chiefly because of Voit's reputation as a successful student of nutrition.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Voit considers that a normal man of an average body weight of 70 to 75 kilos (150 to 165 pounds), doing a moderate amount of work, requires daily 118 gm. of proteid, 55 gm. of fat and 500 gm. of carbohydrate. This gives a total food value of about 3,000 calories and will maintain the body in a good physical condition. The standard introduced by Atwater gives 152 gm. proteid, 125 gm. fats and 400 gm. carbohydrates, affording a fuel value of 3,315 calories.

These standards are based on the idea that from 100 to 118 gm. of proteid or albuminous food is necessary to maintain the body in nitrogenous equilibrium; that is, that the amount of nitrogen excreted through the urine and feces should equal that taken into the body and at the same time the body be maintained in a state of equilibrium as to health, strength and practically also of weight.

Right here it is best to relate the fate of the elements taken into the body. Fats and carbohydrates when oxidized in the body are ultimately burned to simple gaseous products, that is, carbonic acid and water. Consequently the waste from these food products is quickly thrown out of the body without resulting harm to any of the tissues.

If such products are taken in excess, the harm which results will be chiefly in the deposits of fats in an undesirable amount, which would render the body gross and unwieldy. A too large amount taken is very apt to clog the alimentary canal, overfatigue the digestive organs and may undergo abnormal fermentation.

The waste products of proteid foods, when assimilated, consist of crystalline nitrogenous products which ultimately pass out of the body, chiefly through the kidneys. Before their elimination from the body these crystalline elements, which are in some instances toxins, float about through the body and may exercise a deleterious influence on the organism either general or local. The literature is full of theories on the diseases due to many of these crystalline products, chiefly uric acid, urea, the purin bodies, etc. All who are acquainted with these facts have recognized the importance of restricting the formation of the deleterious crystalline waste products by limiting as far as possible the amount of proteids taken into the body.

Until recently it has been the belief that the nitrogenous equilibrium of the body could not be maintained on a less amount of proteids than that given in the standard diet of Voit and others.

Recently some far-reaching experiments have been made on the physiology of nutrition and of metabolism of the body which practically revolutionize the ideas held by most physiologists, and it is the chief purpose of this paper to call attention to these new facts.

They are chiefly contained in an experimental study by Russel H. Chittenden, director of the Sheffield Scientific School of Yale University and professor of physiologic chemistry, on the "Physiologic Economy in Nutrition, with Especial Reference to the Minimum Proteid Requirement of a Healthy Man," and two articles by Otto Folin on studies made in the chemical laboratories of the McLean Hospital for the Insane, Waverly, Mass., on "Laws Governing the Chemical Composition of the Urine" and "A Theory of Protein Metabolism."[1] Bearing on the same subject to a lesser degree is the classical work of Prof. J. P. Pawlow of St. Petersburg, on "The Work of the Digestive Glands."

In the foregoing and in what follows I have made free use of the data found in the above-named books and periodicals and without further acknowledgement of my indebtedness to these eminent writers, I desire above everything else to recommend these books for a careful study by all who are interested in this subject. If this article accomplishes nothing more than to induce this audience to study the works named, I feel that it shall have accomplished a great deal.

With the object of throwing light on the subject of the physiologic economy in nutrition, Professor Chittenden made experiments on three groups of men.

The first comprised a group of five men, of varying ages, connected with the faculty of Yale University, whose work was distinctly mental rather than physical.

Second, a detail of 13 men volunteers from the Hospital Corps of the United States Army, as representatives of the moderate worker. These men were of different nationalities, ages and temperaments.

Third, a group of 8 young men, students in Yale University, all of them trained athletes, as combining the mental worker with a pronounced amount of physical work.

The individuals of these groups were experimented on by permitting them to have first the usual standard dietary, during which urinary examinations were made showing the nitrogen output together with the weight, strength, and physical and mental efficiency of the individual. Then for a long period of months each individual of each group was placed on a dietary which diminished his proteid food to one-half or less even of the Voit standard but permitting the individual freedom in his choice of fats and carbohydrates to the full satisfaction of his appetite. On this dietary the body weight diminished to a very moderate degree in some of the individuals, but soon became constant and the health, strength and efficiency, both mental and physical, was maintained at a higher level than on an ordinary standard diet. On the Voit diet or its equivalent the daily excretion of nitrogen through the urine amounted to at least 16 gm. On the diet with a much lessened amount of proteids the daily output of nitrogen amounted to about 6 to 9 gm. The nitrogenous balance was maintained on this diet, as shown by a practically constant body weight in each individual, especially after the individual had been on the diet for a few days, and by an estimation of the nitrogen output in the urine and feces. The diminution in the nitrogenous waste materials was chiefly in the urea nitrogen. The total output of uric acid in the urine was also diminished. Professor Chittenden did not take an account of the excretion of the kreatinin or of the sulphur compounds, but Folin made such observations, which will be quoted later. Chittenden showed undeniably that the men experimented on, who represented all classes of individuals in reference to mental and physical work, could meet all ordinary requirements of mental and physical labor with a high efficiency on an intake of proteid food far below that of the standard diets. It was found, too, that in the reduction of the proteid it was not necessary for these individuals to increase very much, if at all, the amount of fats and carbohydrates to maintain themselves in good condition.

---

[1] Amer. Jour. of Physiology, vol. xiii, Nos. 1 and 2.

Professor Chittenden comments favorably on the practice of a more thorough mastication, as brought out by Mr. Horace Fletcher "In the A B Z of Our Nutrition" and of the existence of a reflex of deglutition evoked by thorough chewing, which, if properly carried out, produced a very striking effect on the appetite, which was made more discriminating and led to a choice of a very simple dietary and in part reduced the craving for flesh food.

Those who have found it necessary to lavage the stomach of patients have noticed the very common want of a thorough division of the food by mastication, as shown in the large particles of food of all kinds which are found in the stomach of the average individual. This entails an enormously increased work on the digestive organs and one of the salutary lessons of the stomach tube to the patient is to show him the evils of insufficient mastication. That mastication should be carried out to the degree and for the purpose advised by Mr. Fletcher and Dr. van Someren is a question which time must solve. We are too apt to be faddists in many ways, but if the gentlemen named shall influence the observance of the physiologic law of thorough mastication of the food they will have accomplished much good.

Otto Folin, in the analysis of the urine from many individuals on a standard diet, found that the total nitrogen excreted in twenty-four hours averaged, in round numbers, about 14½ to 18 gm. This amount of nitrogen was represented by urea in from 86 to 90 per cent.; ammonia in from 3.3 to 4.5 per cent.; kreatinin in from 3.2 to 4.5 per cent.; uric acid in from 0.6 to 1 per cent. and undetermined nitrogen in from 2.5 to 5 per cent. On a dietary with a minimum amount of proteid, far below that of the standard diets, but still sufficient to maintain nitrogenous equilibrium and practically a constant body weight, the average nitrogen output in the urine diminished to 4 to 8 gm. in twenty-four hours. The percentage of urea nitrogen was now diminished to about 60 per cent.; the ammonia nitrogen was totally diminished, but the percentage was relatively slightly increased. Kreatinin remained the same in absolute quantity excreted. Uric acid was diminished in total amount, but not nearly in proportion to the diminution of the total nitrogen, and the per cent. of uric acid was therefore relatively increased.

In normal individuals, on a standard diet, the total sulphur output was 3 to 3.75 gm. in twenty-four hours. This was made up of inorganic SO_3—ethereal SO_3 and neutral SO_3. Of these, the inorganic SO_3 made up an average of 87 to 89 per cent., the ethereal 5.5 to 8 per cent., and the neutral 4 to 6 per cent. On a low protein diet the total sulphur excreted ranged from 0.77 to 1.50 gm. in twenty-four hours. This was represented by inorganic SO_3, reduced to about 60 per cent. The ethereal increased to about 14 per cent., representing a form of sulphur metabolism more prominent with than without the protein. The neutral sulphur was relatively increased, but the total excretion was the same—that is, unaltered in amount by the reduction in the proteids.

That the above statements may be made more graphic, I copy from Folin's article[2] the following, showing the analysis of the urine from the same individual, taking a standard diet in the first, and when taking the diet, with a much reduced protein in the second column.

	I.	II.
Volume of urine	1170 c.c.	385 c.c.
Total nitrogen	16.8 gm.	3.60 gm.
Urea nitrogen	14.70 gm. = 87.5 p. c.	2.20 gm. = 61.7 p. c.
Ammonia nitrogen ..	0.49 gm. = 39 p. c.	.42 gm. = 11.3 p. c.
Uric acid nitrogen...	0.18 gm. = 1.1 p. c.	0.09 gm. = 2.5 p. c.
Kreatinin nitrogen ..	0.58 gm. = 3.6 p. c.	0.60 gm. = 17.2 p. c.
Undetermined nitrogen.	0.85 gm. = 4.9 p. c.	0.27 gm. = 7.3 p. c.
Total SO_3	3.54 gm.	0.76 gm.
Inorganic SO_3	3.27 gm. = 90.0 p. c.	0.46 gm. = 60.5 p. c.
Ethereal SO_3........	0.19 gm. = 5.2 p. c.	0.10 gm. = 13.2 p. c.
Neutral SO_3	0.18 gm. = 4.8 p. c.	0.20 gm. = 26.3 p. c.

A glance at the table shows clearly the relation of the different forms of N and SO_3 excreted by the same individual on the two diets.

It is shown that the total N excreted is diminished from 16.8 to 3.60 gm.; that urea N is greatly diminished from 14.7 to 2.2 gm.; that ammonia N is but moderately diminished from 0.49 to 0.42 gm.; that uric acid N is diminished one-half, from 0.18 to 0.09 gm., and that kreatinin N is practically unchanged in the total amount excreted. It follows that the percentage relation of the different N bodies is relatively altered—with the marked diminution alone of the urea N.

With the SO_3 output, inorganic SO_3 corresponds in fluctuation in the two diets with urea, ethereal SO_3 with uric acid, and neutral SO_3 with kreatinin.

If one will compare the table of analyses of urine in the reports of Chittenden and Folin they will be found to correspond in the main in reference to the N output. Chittenden's observations were made on individuals over a sufficiently long period of time to show that the result is definite, and Folin's more complete estimation of the different forms in which N is excreted and the relation of one to another affords us data on which a fundamental theory of metabolism may be considered.

There are at present two theories of protein metabolism. According to Voit, protein of the food circulates in the blood and plasma of the tissues, and is there katabolized without becoming an integral part of the cells. Essentially this constitutes chemical decomposition of the protein in solution. The small part of the living cells which dies is dissolved in the circulating medium and becomes a part of the protein derived from the food.

Pflüger's theory is that the circulating protein of the food is first transformed into bioplasm, becomes a part of the living cell and as such is oxidized. Pflüger admits that a part of the protein may be katabolized in solution according to the theory of Voit.

The theory of Pflüger involves an enormous building up of bioplasm, coincident with an equal destruction of tissue. Both theories involve the katabolism of all of the protein of the food, in the tissues where they are utilized.

As Folin says, no fundamental theory concerning protein metabolism can be accepted unless it can be made to harmonize with the laws governing the composition of the urine.

The theories of Voit and Pflüger are based on the assumption that quantitative changes in the total protein metabolism produce no appreciable effect on the percentage composition of urines, representing such metabolism. As announced by Folin, changes in the total amount of N and S eliminated in the urine show a pronounced change in the percentage composition of the N and S.

This seems to prove that katabolism of protein food must be of at least two kinds. The nature of the changes in the distribution of the urinary constituents seems to warrant the statement that the two forms of katabolism are independent. The one is variable in quantity, as represented by urea and inorganic sulphur, the other is constant and yields kreatinin, neutral sulphur and to some degree uric acid and ethereal sulphates.

---

[2] Amer. Jour. of Physiol., vol. viii, No. 2, p. 118.

As is shown in the urine analyses, the more the protein of food is diminished, and therefore katabolism reduced, the more prominent relatively become kreatinin and neutral sulphur the representatives of the constant katabolism.

It has been proved that kreatinin elimination is not diminished, and that some other constituents are but slightly reduced when practically no protein food is given. This shows that there is a constant tissue waste, varying possibly in degree with the wear and tear incident to work, and shows that a certain amount of protein must be furnished with the food to maintain nitrogenous equilibrium.

In other words, katabolic processes which yield the end products that are a constant quantity under varying amounts of proteid food, represent the metabolic processes that constitute an essential part of the activity which distinguishes living from dead cells.

Folin distinguishes the constant protein metabolism, a tissue or endogenous, and the variable protein as an exogenous or intermediate metabolism. The constant metabolism fixes a limit to the lowest attainable level of nitrogenous equilibrium. Just what this level is will depend on how much, if any, urea is derived from the same katabolism which produces kreatinin. When this shall have been determined we shall possess a formula, expressing the point of lowest attainable protein katabolism, because at this point the percentage composition of the nitrogen and sulphur of the urine will be constant. It is plain that a sufficient amount of protein food to maintain the constant protein metabolism will be absolutely necessary.

The existing theories assume that protein metabolism is essentially an oxidation, and that the greatest amount of katabolism takes place in the muscles where the greatest amount of oxidation exists, i. e., the same chemical processes as those which katabolize the fats and carbohydrates.

Folin makes it clear that the splitting of the protein molecule may be more easily accomplished by hydrolysis than by oxidation.

Urea is not found in the muscles except in very small traces. Its absence in the muscles where the greatest katabolism takes place has heretofore not been explained. On the other hand, kreatin is found in the muscles, and its derivative kreatinin is a constant quantity in the urine.

If the katabolism of proteids represented by urea does not take place in the muscles, then it must be that the nitrogen katabolism which yields urea must take place elsewhere by special chemical processes. Furthermore, we are forced to the conclusion that this katabolism is not of such fundamental importance as that which yields kreatinin. It is known that in the digestion of protein, ammonia is directly formed by proteolytic ferments, and that the liver is capable of converting ammonia into urea. It is known, too, that the blood passing from the intestines to the liver contains two or three times as much ammonia as the blood in the hepatic veins.

Furthermore, there is evidence that hydrolytic decomposition of protein occurs in the digestive tract. The first step in the process is the decomposition into proteoses, amido acids, ammonia and possibly urea. Hydrolysis is carried further in the mucous membrane of the intestines, and is completed in the liver, each splitting being such as to further the formation of urea. By this means the unnecessary nitrogen is removed, and it explains the fact that the animal organism tends to maintain a nitrogenous equilibrium within the wide limits of forced feeding, on the one hand, and of low protein food experiments on the other.

An excess of protein in the food is not stored up in the body as such, for the actual need of nitrogen is very small, as it is limited to the actual building up of the cell bioplasm. It is not necessary to store it in the body, because an excess of nitrogen is always furnished with the food. A larger nitrogen intake than is necessary to meet the needs of endogenous metabolism will lead only to an increase in the elimination of urea. It can not increase the tissue metabolism and the resulting formation of kreatinin.

The katabolism of fats and carbohydrates is accomplished chiefly by oxidation. The process sets free a large amount of heat, which may be converted into mechanical energy. In the removal of nitrogen from protein by hydrolysis but little energy is expended. The non-nitrogenous rest of proteid decomposition by hydrolysis affords a substance which may be further partly converted into fats or carbohydrates. It then becomes subject to the same laws governing the katabolism of fats and carbohydrates. The organism may at any time be made to store up fats and carbohydrates, if an excess over the requirements is taken. It has already been stated that this excess may be taken without fear of poisoning the body, because the waste from them consists of non-crystallizable products. An excess may overburden the digestive organs and cause abnormal fermentation or tire out the glycolytic function. Too large a deposit of fat may render the body unwieldy and may infiltrate and physiologically embarrass the muscles and viscera.

NITROGENOUS EQUILIBRIUM.

The above theory of metabolism of Folin explains the persistent tendency of the normal body to maintain nitrogenous equilibrium when a large amount of proteid is consumed, even when this involves the formation of an excessive amount of urea.

If one will examine the tables of the feeding experiments made by Folin and compare the nitrogenous output on the low protein diet with the nitrogen excreted in the urine on a resumption of a free amount of protein in the food, it will be seen that the elimination of nitrogen was more than doubled on the first, and on the second day there was more than three times as much excreted as on the last day of the low protein diet.

Folin offers the following explanation:

> All the living protoplasm in the animal organism is suspended in a fluid, very rich in protein, and on account of the habitual use of more nitrogenous food than the tissues can use as a protein, the organism is in possession of approximately the maximum amount of reserved protein in solution that it can advantageously retain. When the supply of food protein is stopped, the excess of reserve protein inside the organism is still sufficient to cause a rather large destruction of protein during the first day or two of protein starvation, and after that the protein katabolism is very small, provided sufficient non-nitrogenous food is available. But even then, and for many days thereafter, the protoplasm of the tissues has still an abundant supply of dissolved protein, and the normal activity of the muscles is not impaired. When 30 or 40 gm. of nitrogen have been lost by an average-sized man during a week or more of abstinence from nitrogenous food the living muscle tissues are still well supplied with all the protein they can use. This is proved by the unchanged kreatinin elimination and by the fact that the individual feels no unusual fatigue or inability to do the customary work.

The organism at the end of a low protein diet experiment still has an abundance of available protein in the nutritive fluids, and this is why it only gradually and only under the pressure of an excessive supply of food protein again acquires the original maximum store of this reserve material.

Based on the above interpretation of metabolism and nitrogenous equilibrium, the so-called standard diets are unnecessarily rich in proteids. It is necessary to supply protein in the food in sufficient amount to provide liberally for the endogenous or tissue metabolism and to maintain a reserve protein in solution. If the blood is in need of tissue builders, the organism can rapidly assimilate large amounts of nitrogenous food. This is clearly shown in emaciated conditions following fevers, surgical operations, etc., for during convalescence there is often a ravenous appetite and a rapid increase in weight and strength with a corresponding retention of nitrogen.

The main contention of Voit and others is that it is necessary to consume 118 gm. of proteid daily in order to maintain a nitrogenous equilibrium and at the same time preserve a condition of health and mental and physical efficiency.

The experiments of Chittenden are so decisive that a proteid rich diet is proved not to be necessary. He is unquestionably right in the conclusion that the standard diet may be divided by two, as far at least, as the proteids are concerned.

The practical results of the experiments of Chittenden are made more rational and clear by the researches and deductions of Folin.

THE DAILY DIET.

Chittenden maintains that the daily requirement is not only much less of protein than that recognized in the standard diets, but that the fats and carbohydrates also may be considerably diminished.

We recognize the fact that the diet must differ for individuals, dependent on the occupation, the season of the year, the climate, etc. However, the modification in the diet will consist chiefly in the variation of the amount of fats and carbohydrates rather than a change in the quantity of the proteid. Folin has shown that physical activity does not cause a material tissue waste of muscle, for kreatinin is not appreciably increased in the urine by physical labor. The growing individual and the emaciated convalescent only can utilize a large nitrogen intake and retain it. The difference in the dietary of grown normal individuals will consist mainly in the fuel foods—the fats and carbohydrates.

The achievements of the Japanese on a diet chiefly carbohydrate is sufficient proof that a high efficiency, both mental and physical, may be maintained on a low proteid and full fuel diet.

If a large proteid diet is unnecessary, is it also detrimental? In the light of the theory of exogenous metabolism of Folin, an excess of proteid furnished with the food is normally rapidly converted into harmless urea and is quickly eliminated by the kidneys.

The excessive production of uric-acid, xanthin bases, kreatin and other so-called extractives is looked on as the cause of gouty and other so-called autointoxication diseases. The excessive production of these substances is usually ascribed to an excess of proteid consumed. These substances are the result chiefly of the endogenous metabolism, and, scientifically speaking, have no relation to an excess of protein, for that substance is converted into harmless urea. However, the meats contain considerable extractives or substances out of which they may be formed, and therefore an excess of concentrated protein food in the form of meat may result in such an autointoxication. The continued excessive use of protein may lead in time to the accumulation of a larger amount of reserve protein than the organism can retain in the fluid media. The continuous presence of such a large unnecessary supply of unorganized reserve material may weaken one or all of the living tissues.

We are the creatures of habit. With palates craving for new sensations and the prevalent belief that hearty eating promotes health and strength, it is no wonder that we eat too much. It is proper, too, that the pleasures of the palate should be gratified. The pleasure which eating affords promotes digestion. Bolting does not permit proper enjoyment of food. Thorough mastication undoubtedly makes the palate more discriminating and serves as a check to overindulgence.

Chittenden says: "Physiologic economy in nutrition means temperance and not prohibition. It means full freedom of choice in the selection of food. It is not a cereal diet nor vegetarianism."

Practical application of the newer ideas of metabolism and nutrition to diets in disease could be readily made, but are outside of the limits of this paper.

METHODS, VALUE AND LIMITATIONS OF THE KNOWLEDGE OF THE GASTRIC CONTENTS.*

GEORGE DOCK, M.D.
ANN ARBOR, MICH.

I think it will be admitted that instrumental and laboratory examinations with reference to the stomach are unduly neglected in practice. The reasons for this are similar to those that cause the neglect of other diagnostic manipulations—technical difficulties, real and imaginary, and erroneous views as to clinical value. Many fail to make examinations of stomach contents solely because they think the passage of the stomach tube is difficult and often objected to by the patient. Contrary to this view, I find very few people who require any persuasion and still fewer who offer serious verbal or physical difficulty. Out of many thousands examined, I have encountered only two people in whom I could not successfully use the stomach tube at the first trial. I am not considering, of course, the very important contraindications to the use of the tube (necessary to remember in every case), or real obstructions to the passage.

A belief in the excessive technical difficulties of the examination of the stomach contents depends chiefly on lack of training and of practical experience in the necessary manipulations, which are not essentially as difficult as some of the methods proposed may indicate. An important cause of neglect comes from disappointment at the results. Those who expect to make complete and satisfactory diagnoses from single features, as Bright's disease from albuminuria, diabetes from glycosuria, or pneumonia from crepitant râles, discard gastric diagnostic methods when they find out that absence of free HCl does not positively mean cancer. We still find evidences of a belief in the existence of diagnostic signs, in the advocacy of tryptophan reaction, and others, but the probabilities are that in stomach diagnosis, as in other lines, the greatest assistance will come from patient efforts to appreciate the alterations of function and structure primarily, and by allowing our diagnosis to grow out of these findings, assisted by the other clinical features of the case. An appreciation of gastric physiology confirms this *a priori* view. The important rôle of HCl in the stomach contents suggests in the very beginning the usefulness of an examination into the presence, amount and condition of this, whether partly free or only combined or absent. Clinical experience, I think, confirms this, but there are many who fail to realize it. Thus it happened that at an early period, the absence of HCl in cancer of the stomach was noted, and many people grasped at this as a diagnostic feature, and even yet use it as such, although its limitations have long been abundantly demonstrated. On the other hand, some have gone to the opposite extreme, and, discovering the limitations, reject all stomach examinations as useless. Both are wrong. The absence of HCl in cancer is so frequent, and when it does exist, so constant from day to day, as to form a valuable aid, but there may be cancer present with HCl secretion preserved for a long time, even in excess of the normal amount. But such exceptions and contradictions occur in all branches of diagnosis, and should teach us to discover other details, rather than lead us to a condition of despair. I do not think it necessary at this time to give any statistics as to the relative frequency of the presence or absence of HCl in cancer; for, while interesting and valuable, they do not apply to an individual case. In the examination of a patient we can not give up a diagnosis because of a negative result in one sign. We have still to work out all the signs and only then to attempt the final diagnosis.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

In gastric ulcer the excessive secretion of HCl has so often been noted that it is rightly considered one of the signs of the disease, and yet I could cite a number of cases, confirmed by operation, in which there was no excess in repeated examinations. That single or few examinations may be misleading can be shown by some cases in which variations occur, as from 26 to 88 in the course of seven tests extending over ten days. In diseases like cancer and simple ulcer there are such urgent reasons for early diagnosis that all the other diagnostic features should be used as quickly as possible whenever these diseases are suspected, and in these the complete routine examination of the stomach contents will almost always prevent error from exceptional behavior of the HCl.

The value of estimations of HCl, in my opinion, is greatest in functional diseases of the stomach, or perhaps it would be more exact to say cases in which the stomach functions are altered, without gross organic disease primarily in that organ, though there may be functional or organic disease in other organs that may have a part in the production of the gastric anomaly. These conditions are very common, much more so than is often supposed. Excessive secretion of HCl, for example, is a very common condition. While it may be associated with organic changes in the stomach, such as ulcer, spasm of the pylorus, retention, stagnation and dilatation, yet there may be no gastric symptoms, or only trifling ones, for it also occurs with distant symptoms, such as headache (often simulating ocular headache), severe neurasthenia sometimes, in the male, associated with functional impotence, and hence the cause of ill-directed and not rarely harmful treatment. Thorough examinations of the stomach, made as a routine measure, sometimes lead quickly to improvement of all the subjective symptoms. Even when the gastric symptoms are marked, test meals with complete examinations are indicated. While the picture of marked gastric hypersecretion is often very typical, I have seen cases that had not been differentiated before by other physicians, and that I could not differentiate without test meals, in which the primary conditions were just the opposite—absence of HCl with excessive production of organic acids.

There are also very troublesome cases of functional gastric disease in which the chemical conditions vary. Hypersecretion and hyposecretion or even achylia may alternate in a way only to be followed up by repeated examinations. In the case of organic diseases of the stomach, the further steps are comparatively independent of HCl determinations, but even in these occasional tests are useful. In functional diseases the greatest results often follow frequent estimations of HCl, under various kinds of dietetic and other treatment, and with various test meals. The treatment should be begun as early as possible, sometimes before the first test meal, and used as a factor in the examinations.

There is still room for further investigation in the methods of gastric chemical examinations, and those who have the proper training and facilities can with great advantage pursue such investigation. The general practitioner, however, need not be discouraged because of the possibilities of future discovery, nor prevented from carrying out the methods now available, for these are sufficiently accurate for clinical purposes and not too intricate for any one, and the application of all I shall mention does not require as much time as it does to speak of them. For the primary reaction, litmus paper should be used, and for the presence or absence of free HCl, Congo paper or solution may follow, though this can be dispensed with. Those working with it can learn much from this test. The more accurate and delicate Guenzburg's reagent should always be used. It is so delicate and exact that I can not understand its frequent neglect. This may be due to erroneous results from using a decomposed solution. The tendency to decompose is a drawback, I admit, but it is so easy to test the solution with a drop of dilute HCl that the fault is a trifling one.

Given free HCl, it is next necessary to determine its amount, and for this the dimethyl-amidoazo-benzol is most satisfactory, though it requires the usual care in practicing with test solutions to get the proper end reaction. For the total acidity the phenolphthalein reaction is used. Tests for the combined HCl are not necessary if there is free HCl, hence all of the steps of Toepfer's method are not required in ordinary clinical work. If there is no free HCl, the qualitative Sjoequist test should be applied. Quantitative estimations for combined HCl are not, in my opinion, of clinical necessity, and in order to be accurate, and hence of value, require more chemical experience than the general practitioner need be expected to have. With proper apparatus and reagents, any one can easily acquire sufficient experience in the estimation of HCl to utilize that substance in diagnosis, and with such experience the quantitative tests can often be omitted. Of abnormal or pathologic acids, lactic is the only one requiring chemical tests, for though acetic acid or butyric acid often occur in large quantities they can be detected by the odor. Lactic acid tests to be most useful should be made on a lactic-free test meal, such as shredded wheat or the Boas gruel. Quantitative methods are not necessary, as the relative intensity of the reaction with Uffelmann's or Kelling's test give sufficient indices, though Strauss' burette may be used. The determination of pepsin is not necessary in ordinary work, since pepsin is rarely absent when HCl is present in sufficient quantities, but the method of Mett is often a useful addition to other tests in obscure functional diseases. It is fairly easy to work, and, with the valuable details regarding time-limit worked out by my colleague, Dr. Cowie, requires very little time. The existence of the digestive functions and their relative completeness can easily be shown by the biuret and starch tests, and by the changes in the cells of the gastric contents as observed in the microscopic examination. At the same time the experimenter may have his attention called to the advantage of further work with the functional tests proposed by Sahli, some of which promise useful additions to our diagnostic methods.

If I have spoken of chemical tests first it is not because I look on these as all-sufficient, but rather because they are simple and the results are easily expressed in figures or symbols; but without other observations they are of little or no value. The other tests require practical knowledge and experience. Nevertheless they will repay one the time spent in becoming familiar with them either in a clinical laboratory under the supervision of an expert or worked out with the aid of textbooks and clinical material without such supervision. One quickly learns the normal limits regarding the amount, color, consistency and odor of the gastric contents. From these the need of further examinations becomes quickly known. An excess of mucus can also be recognized, and along with this, the fact that it is not always easy to draw a positive conclusion from such an excess. In the first place, it is always important to exclude an origin from the nose, pharynx or bronchi; in the next place it is necessary to be sure that the excess has not been caused by awkward manipulation of the tube, even if unavoidable. But even if we can exclude such factors, it is important to remember that the presence of even considerable mucus does not warrant a diagnosis of chronic gastritis. Blood is easy to recognize when present in large amounts. Small quantities of blood, due to scratching with the end of the tube, are usually easy to recognize. The tests for occult blood developed in the last few years are of considerable clinical value, though it is, of course, necessary to exclude traumatism. The presence of pus is always important, but here, too, we must be able to exclude an origin from the respiratory tract. The appearance of the other cells mixed with the pus, dust pigment and also a greater variety of bacterial forms than occurs in stomach contents, serve to differentiate. The examination of bits of mucosa is not of very great clinical value. In about one-third of the cases in which such specimens have been examined in my clinic, the microscopic examination of the bits coincided with the other findings. But, on the whole, such examinations do not repay the time spent on them, for purposes of practical diagnosis. The examination of the bacteria in the stomach contents is of only limited value. Staining is rarely necessary, though the Wright stain is easy to apply, and stained preparations will be preferred by those who have not had considerable experience with fresh material. Large numbers of bacteria in the stomach contents, however, throw an important light on the question of stagnation, and there are certain variations in the flora in different cases that are of a good deal of aid in diagnosis. So the Oppler-Boas bacillus, and, on the other hand, yeasts and sarcines, often occur in such large numbers as indicate pretty accurately the chemical and anatomic alterations present. Protozoa also have only a limited diagnostic value, but their occurrence in the stomach is interesting, and the study of cases in which they occur may throw a good deal of light on hitherto obscure processes in that organ. The testing of the freezing point of stomach contents or of its surface tension may furnish a useful possibility of work for those who have time, but at present these possibilities are not necessary for clinical work.

In conclusion, my opinion is that examinations of the gastric contents give information that can not be obtained in any other way, and, though often negative, can not be excluded without risk of serious error. Such examinations are indicated in all stomach syndromes, in all diseases seriously affecting metabolism and nutrition, and in all diseases that affect the function of the stomach, notably diseases of the lungs, heart, liver, kidneys and blood.

CERTAIN NON-GASTRIC DISEASES WITH GASTRIC SYMPTOMS.*

J. H. MUSSER, M.D.
PHILADELPHIA.

The subject is so vast that a certain amount of abruptness is necessary in the presentation. Some of the minor non-gastric diseases with gastric symptoms may be omitted. The question is a study in etiology. In one sense it may be said the account is to include gastric disorders which are secondary to other diseases. It is not to gastric disorders, but to diseases, remote from the stomach, which have gastric symptoms, that we call attention. Strictly speaking, the gastric symptoms are not due to any organic disease of the stomach; but such division is largely arbitrary. No pronounced gastric symptoms are liable to prevail without either irritation, congestion or inflammation, whether the symptoms are temporary or permanent.

It is understood, then, that the ailments considered are those which have for their chief, and for the time dominant, expression, gastric symptoms; it is the class to which, in loose terms, we say it is not your stomach, but your eyes, or your lungs, or your kidneys that are at fault. The patient's sensations direct him to the stomach alone. We must clearly understand that, although we decide that the gastric symptoms are the minor factors, from the standpoint of therapeutics, we must direct treatment as boldly to their alleviation as to the primary disorder. The eyes may be corrected, but the gastric symptoms only mitigated.

NON-GASTRIC ORGANIC DISEASES PRESENTING GASTRIC SYMPTOMS.

The Eyes.—The subject is familiar to all. Who has not seen correction of errors of refraction relieve so-called "bilious attacks," periodical vomiting, anorexia, indigestion and other gastric symptoms? The cure of grave organic ocular defects relieves similar gastric conditions.

The Ear.—The vomiting of middle-ear disease, of disease of the attic and of auditory-nerve affections is well known.

The Nose and Throat.—Morning nausea, loss of appetite and chronic dyspepsia secondary to the pharyngitis of smokers, occurs to all. The gastric disorders of adenoid disease must also be emphasized.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Fifty-sixth Annual Session, July, 1905.

Nervous System.—I can refer only to the gastric crises of locomotor ataxia; the gastric symptoms of bulbar palsy; the occurrence of vomiting, often for six hours before an attack of apoplexy;[1] the vomiting of meningitis, tubercular and cerebrospinal; the gastric symptoms of brain tumor, and those which precede a fully-developed epilepsy. The call can not be too loud to this latter ailment. Such incidents as periodical attacks of indigestion or of vomiting may precede or attend obscure forms of epilepsy. Patients with the peculiar chewing and rumination in that form of epilepsy to which Spiller has recently called attention are usually treated for stomach disorder. The nocturnal and intermittent character of the attacks, the clinical course and the occasional occurrence of a true attack, with other s[illegible]. such as the aura, somnolence and [illegible] event, suggest the true nature of the affection. In children, the occurrence of gastric symptoms, admittedly not of local origin, must demand an examination of the nervous system.

The Cardiovascular System.—The acute affections may have epigastric pain and vomiting as sole expressions of the disorder.[2] More pronounced and continuous are the gastric symptoms, often dominating the picture, in failure of compensation. It is not infrequent that dyspnea, palpitation, cardiac pain or dropsy are absent, and yet dilatation of the heart and secondary portal congestion are present and cause gastric symptoms, as pain, vomiting, hemorrhage, loss of appetite, and symptoms of catarrhal gastritis, as the only symptoms of the heart disease. Many patients with dyspepsia and gastritis may be cured with digitalis.

The Lungs.—Apex pneumonia (pneumococcus infection) and tuberculosis are examples; and, in children with severe vomiting, the possibility of the former infection should be borne in mind.

The Liver.—Organic disease and cholelithiasis have their gastric symptoms.

The Intestines and Appendix.—The recent literature is replete with information and common experience leads to an investigation of these structures in acute and chronic gastric disorders.

The Genitourinary Tract.—The gastric manifestations are well known. A renal calculus, an acute or chronic nephritis, may have vomiting, nausea, anorexia or the gastric neuroses as most marked symptoms. Is not uremia often attended by gastric symptoms only?

The Blood.—Iron cures many, many patients with gastric disorders. The perverted appetite and the nausea and vomiting of chlorosis are familiar.

The Infections.—I shall only call attention to the importance of the possible occurrence of gastric symptoms alone in the early periods of the eruptive fevers. Time compels exclusion of uncinariasis, malaria and other infections, and admits of only a word regarding tuberculosis, gonorrhea and syphilis. Tuberculosis must never be excluded as a possible factor in the production of gastric symptoms. Who has not seen advanced phthisis treated in the early periods of disease for gastric symptoms alone? In young adults, the temperature alone may guide us to a conclusion.[3] The causeless anorexia, the dyspepsia, the morning nausea, and the vomiting may attend early tuberculosis and precede pulmonary symptoms and physical signs. Syphilis is often marked by gastric symptoms, independently of the medication which often causes them. Gonorrhea requires more than a passing notice. In late adult and in early middle age, toxic gastric symptoms occur and continue unrelieved until, if possible, the deep urethral infection or prostatic infection is cured. The history and the urine may disclose the cause.

The Intoxications.—To the toxemia of the infections we must add those due to tobacco and to lead, as in the achylia of plumbic gastritis, as pointed out by Sailer. The objective signs of lead poisoning may be most obscure. Exophthalmic goiter gives rise to pronounced symptoms of gastric character alone, the other phenomena being in abeyance. Protracted vomiting may be of such origin and require careful examination to disclose the source. The presence of pus somewhere will give rise to gastric symptoms, and I have long taught that anorexia is often due to internal suppuration.[4] Addison's disease may cause toxic gastric symptoms while uremia is a classical cause.

NON-GASTRIC CONDITIONS ATTENDED BY GASTRIC SYMPTOMS.

To this division belong that very large class of cases to which the term gastric neurosis is applied. Gastric symptoms may be the only manifestation of hysteria and of neurasthenia. The gastric neuroses are the most difficult to understand. Unfortunately time forbids any complete discussion.

ACUTE GASTRIC MANIFESTATIONS SIMULATING PRIMARY ORGANIC GASTRIC DISEASES OR ACUTE PHASES THEREOF.

In these days of surgical alertness it must be borne in mind that acute surgical affections of the stomach may be simulated by a symptom-complex caused by disease elsewhere.

Cirrhosis of the Liver.—Gastric incidents in its course, as pain, vomiting and hemorrhage, acute in onset, may simulate gastric ulcer, with or without perforation.

Uremia.—Epigastric pain, vomiting, hemorrhage and collapse may occur, simulating gastric ulcer and perforation.

Locomotor Ataxia.—The gastric crises simulate acute gastric lesions and may appear like ulcer.

Gastric Neuroses.—The gastric neuroses of hysteria, neurasthenia and epilepsy simulate ulcer at times.

DIAGNOSIS.

Non-gastric diseases with gastric symptoms can only be recognized after an examination of all the organs of the body and a study of all excretions and secretions. The clinical course and the historical features are essential. The symptoms bear more or less relation to physiologic or pathologic fluctuations of the primary source of the disease, as of the eye, heart, kidneys, etc., and are not of the constancy of organic disease of the stomach. The gastric neuroses are inconstant as to character, irregular as to manifestation, both subjective and objective, and have a relation to emotional or psychic influences which require all the skill, genius and patience of the practitioner accurately to disclose.

FOOD STAGNATION FROM ALL CAUSES.*

CHARLES G. STOCKTON, M.D.
BUFFALO, N. Y.

When the stomach fails to empty itself within a reasonable time after the taking of food, this condition is termed food stagnation. It differs in degree, depending, in part, on the character of the food taken, still more on the morbid state giving rise to the condition. Semi-liquid or pultaceous food should leave the stomach in four or five hours, and if it is retained longer there is a certain degree of stagnation. An ordinary meal composed of a variety of foods is the proper test for food stagnation. With this meal the stomach should be emptied, according to Riegel, within seven hours, and the presence of contents beyond that time is evidence of food stagnation. There are conditions, however, in which the liquid food is retained for a much longer period than five hours, and solid foods are retained for twenty-four hours or longer. Under such circumstances, we have to deal with more serious cases.

ETIOLOGY.

Food stagnation is one of the most important of the gastric disturbances. It invariably gives rise to symptoms both local and general. Locally, the patient experiences distress and a sense of weight, sometimes pain, together with eructations of gas, regurgitation of the stomach contents, and often vomiting. In certain cases the stomach behaves in a lifeless, inactive manner; in other cases it takes on violent movements which the patient may feel and which the observer may perceive through the abdominal parietes. Constitutionally, there are usually found evidences of autointoxication and starvation. These symptoms vary widely in different cases, depending on the degree of stagnation and on the character of the fermentation that may be present. The nature of food stagnation differs, as does its cause, and many conditions may lead to it. Cases may be roughly divided into two classes: First, those in which stagnation results from depression of the motor function of the stomach, without the presence of any actual obstruction. The stomach walls are simply too feeble to overcome the slight retention, or holding back, exercised normally by the pylorus. Second, those in which there is actual obstruction to the outflow of stomach contents, regardless of the kinetic energy of the gastric walls. There are certain cases in which we have to deal both with atony of the gastric walls and with obstruction at the pylorus. More often these cases begin with obstruction and the atony appears as a secondary matter.

Food stagnation is often associated with dilatation of the stomach, but on the other hand, there may be a large stomach without stagnation, and there may be very marked stagnation without gastrectasis. It is for this reason that Einhorn prefers to use the term ischochymia in the description of many cases formerly classified as ectasy, and it is this view which has led to the discussion of food stagnation as an entity; whereas, it was in former times almost invariably spoken of as an attribute of dilatation of the stomach.

Of the cases of the first class, anything which leads to the weakening of the muscular layer of the stomach may act as a cause. It, therefore, follows some cases of gastritis when the inflammation has invaded the muscle layers. It results from degeneration of the gastric muscle from any cause, and, therefore, occurs in grave anemias, inanition, severe intoxications and infections. It occurs in cases of great depression, more often when this is prolonged, sometimes when it is brief, but acute, as in surgical shock, even though the stomach itself is not involved in trauma, or operation. I have known it to occur in acute illnesses without previous history of stomach trouble. Occasionally it appears to be congenital, and there are instances which seem to be hereditary and in which it occurs in a number of individuals of the same family. It may follow from adhesions to the stomach, thus making expulsive efforts ineffectual. It may result from imperfect innervation, and this may occur in consequence of general or local nervous depression. It most often results from overtaxation of the stomach; for instance, from eating or drinking excessively, especially the former, or from eating very coarse foods. This cause is naturally most operative when the functions of the stomach are depressed and systemic energy is on a low plane. The condition is, therefore, not infrequently induced by feeding abundantly too coarse food to convalescents. I have known it, for instance, to occur from overfeeding during or after typhoid fever. I knew a fatal case which followed the taking of a Christmas dinner by a convalescent from pneumonia. In every-day practice we most often find this type of food stagnation developing in people of lowered energy, such as is produced by overwork, mental or physical, excessive venery, etc., who at the same time are indiscreet in the quantity and quality of food taken.

As to the second class of causes of food stagnation, the most common is cicatricial pyloric stenosis, secondary to gastric ulcer. This sometimes arises from healed and sometimes from active ulcer, and chronic irritation or inflammation at the pylorus occasionally leads to the same result without the intervention of ulcer. There are a few instances in which we have to deal with benign hypertrophy of the pylorus with exaggerated action of the pyloric sphincter, giving rise to a palpable tumor and to disharmony between the detrusor and the sphincter apparatus of the stomach, the nature of which hypertrophy is not well understood. In some there is a congenital hypertrophy of the pylorus which may lead to fatal vomiting in the new-born, or later in life may develop into incoercible vomiting. A frequent form of obstruction is found in pyloric spasm, the result of oversensibility of the pylorus, either from erosions of the mucosa or simply from nervous hyperesthesia, more often associated with hypersecretion and hyperacidity of the gastric juice. In other words, the condition is found in gastrosuccorrhea and in hyperchlorhydria. The trouble may result from perigastritis with contracting adhesions, from band-like adhesions constricting the pylorus or duodenum, or from pressure exercised by tumors, or other processes, on these parts. The obstruction may occur some distance below the pylorus, thus giving rise to stagnation of the duodenal contents, as well as the contents of the stomach. Cancer of the stomach is a common cause of the conditions. Before a palpable tumor appears, there may occur spasm of the pylorus arising from its irritability. This may at first be transient in character, thus misleading the clinician. Gastroptosis, with the sharp bend in the pylorus or duodenum, is sometimes a cause, but its actual occurrence must be very rare.

MORBID ANATOMY.

The morbid anatomy of motor insufficiency of the stomach varies according to the nature of the case. In the early stages of gastric atony no change will be found in the structure. In advanced cases the stomach is likely to be found dilated, with more or less thinning of and, perhaps, fatty or fibroid degeneration of the muscle walls. The mucous membrane frequently shows the evidence of chronic gastric catarrh, with fatty or fibroid changes. When the stomach dilates, it is not always in the same direction, but is in the line of least resistance. More often the enlargement occurs around the greater curvature and fundus, although it may be at the antrum pylori or even upward toward the diaphragm.

DIAGNOSIS.

The diagnosis of stagnation is not difficult; it may be suspected when patients complain of eructations of food taken a long time previously. It can be demonstrated only by the use of the stomach tube. If the greater part of an Ewald test breakfast is found present three hours after eating, a moderate insufficiency is present, or if the stomach is not emptied seven hours after a hearty mixed meal the same conclusion is reached. The degree of food stagnation may be inferred from the amount of food found present; that is to say, if the stomach is found nearly empty, the insufficiency is small in degree; if, however, the greater part of the meal remains, the extent of the disability should be measured accordingly.

It is a good plan to examine the stomach in the morning, fasting. If the usual evening meal has been taken, and the stomach is found empty in the morning, the stagnation is not great. In most cases, in addition to the estimation of the motor insufficiency of the stomach, one passes to an examination to determine the size and position of the organ and to ascertain the state of the gastric chemistry. These features, while having an important bearing on the individual case, are not necessarily related to the food stagnation. Nevertheless, every case in which food stagnation occurs should have the most complete examination, not only in reference to the stomach, but to the organism as a whole. There is a very close relation between the systemic and gastric conditions.

TREATMENT.

The treatment of food stagnation or motor insufficiency is a broad subject and can not be fully discussed at this time. There are some principles which are so important that they should receive attention to the exclusion of details. In the first place it must be remembered that gastric atony may be but a part of a general atony, and gastric weakness but a part of general weakness. On the other hand, there are cases in which the organism seems strong, but in which the motor power of the stomach is insufficient, and this without any unusual obstruction. Whether the atony is limited to the stomach or but an expression of the general debility, it is always of the utmost importance to manage the organism as a whole so as to increase energy and prevent its dissipation. In those cases where the stomach seems alone involved in the muscular weakness, local attention is, of course, especially demanded. The motor power may be assisted by certain mechanical measures, especially by really skillful massage over the region of the stomach, by trunk rotation and flexion, and by the alternate hot and cold douche over the epigastrium, and by external and internal faradization. The alternate hot and cold douching through the stomach tube has seemed sometimes to do good. As for drugs, undoubtedly benefit follows the use of the simple carminatives, bitter infusions, and temporarily the diffusible stimulants. These measures must be modified according to whatever other condition may be associated with the motor insufficiency; as, for instance, catarrhal gastritis, carcinoma, ulcer, ptosis, etc. It should here be reiterated that failure or success depends more on general management of the patient, on proper rest, exercise, recreation, diet, mental state, etc., than on the mere local treatment of the stomach. Of course, both must receive consideration.

Surgery has little place in this form of motor insufficiency. As for those cases depending on obstruction, surgical intervention is often of the utmost value; yet I can not agree with the dictum that all such cases are suitable to surgical relief. Where it depends on spasm of the pylorus from overirritability of tissue, whether from hyperchlorhydria, hyperesthesia, or simple erosion of the pyloric mucosa; surgery ought not to be considered; yet I have known these cases sent to the surgeon. There is no artificial drainage of the stomach which compares in efficiency with the normal. The proper treatment consists in lowering the acidity of the gastric secretions, soothing the gastric mucosa and the selection of an unstimulating liquid or very soft diet which is free from all irritating particles. Lavage followed by soothing lavements of the mucous membrane is of great assistance. I have seen cases, which at first suggested serious organic disease of the pylorus, improve promptly under this treatment and know that the patients have continued without disturbance for years afterward. When there is ulcer at the pylorus, the question is more difficult. The present tendency, of course, is to operate at once, and ulcer of the pylorus is an ugly affair; yet in some cases in which the ulcer is small and yields readily to treatment it is probably wise to follow the conservative method, keeping the case for a while under observation before resorting to a gastroenterostomy. We are beginning to find out that a stomach on which a gastroenterostomy has been performed is by no manner of means as good as a normal stomach. If, however, the ulcer continues to give trouble, if pain and spasm frequently recur, I would recommend pyloroplasty (if the ulcer can be safely excised), otherwise gastroenterostomy. In benign hypertrophy of the pylorus without ulcer, I advise operation, preferably pyloroplasty. When there is cancer of the pylorus, excision followed by gastroenterostomy is probably, on the whole, the wiser course. If there is extensive involvement, gastroenterostomy alone often allows a year or more of comparative comfort to the patient. I have seen some brilliant results, but more depressing failures. Of the latter, it is only fair to say that by the operation there is little to be lost and possibly a year to be gained. In atonic cases, especially when associated with ptosis, some benefit follows from change of posture; and at times Rovsing's or other operations that raise the distended fundus, thus enabling the organ to drain, are of use.

Something should be said as to vomiting in this condition. It is often a most conspicuous symptom, but varies much in its characteristics in different cases which appear to be of the same kind. Occasionally vomiting occurs only when the stomach is overdistended; at other times there are periods of great gastric irritability, with retching, even when the stomach is empty. In obstructive cases the nausea and vomiting often depend on yeast fermentation, and, with the exception of lavage, nothing gives so much relief as salicylic acid, which overcomes the yeast fermentation. Even when lavage is indicated, the relief afforded is greatly enhanced by the addition of this drug.
